(Received May 21, 2015)

Abstract. We study improper interval edge colourings, defined by the requirement that the edge colours around each vertex form an integer interval. For the corresponding chromatic invariant (being the maximum number of colours in such a colouring), we present upper and lower bounds and discuss their qualities; also, we determine its values and estimates for graphs of various families, like wheels, prisms or complete graphs. The study of this parameter was inspired by the interval colouring, introduced by Asratian, Kamalian (1987). The difference is that we relax the requirement on the original colouring to be proper.

Keywords: edge colouring; interval colouring; improper colouring
MSC 2010: 05C15

## 1. Introduction

Throughout this paper, we consider simple connected graphs without loops or multiple edges; we use standard graph terminology from book [4].

A proper edge colouring $c: V(G) \rightarrow\{1, \ldots, k\}$ of a graph $G$ which uses each colour from $\{1, \ldots, k\}$ at least once is called an interval colouring if for each vertex $x$ of $G$, the set of colours of edges incident with $x$ (the palette of $x$ ) forms an integer interval; we say that the graph $G$ is interval $k$-colourable. For an interval colourable graph $G$,

This work was supported in part by French national agency for the promotion of higher education, international student services, and international mobility under the bilateral contract No. 31777QK, by Slovak Science and Technology Assistance Agency under the bilateral Slovak-French contracts Nos. APVV-SK-FR-2013-0028, VVGS-PF-2014447, VVGS-2014-179 and VVGS-PF-2015-484. Also, this study has been carried out with financial support from the French State, managed by the French National Research Agency (ANR) in the frame of the "Investments for the future" Programme IdEx Bordeaux-CPU (ANR-10-IDEX-03-02).
let $t(G)$ denote the maximum number of colours used in any interval colouring of $G$. The notion of interval colouring was introduced by Asratian and Kamalian in [1] in connection with specialized scheduling problems and, since then, it was further investigated in many papers, see for example [3], [5], [6], [7], [8], [9], [10]. Not all graphs are proper interval colourable (this concerns, for example, graphs of Class 2); in fact, the problem of determining whether a graph has an interval colouring is NP-complete, even for bipartite graphs, see [2] and [11].

In our paper, we relax the requirement on the above defined colouring to be proper and introduce the parameter $\hat{t}(G)$ being the maximum number of colours in an improper interval colouring of $G$. Note that $\hat{t}(G)$ is defined for every graph (which is in sharp contrast with $t(G)$, see [3]) and is at least 3 for all graphs of order at least 3 different from $K_{3}$. Also, for a graph $G$ which is interval colourable, $t(G) \leqslant \hat{t}(G)$ holds. Compared with the range of results for interval colourings, it seems that improper interval colourings have not been studied yet. Our aim is to contribute to this topic by determining the exact values of $\hat{t}(G)$ or their estimates for graphs of several classic families (this concerns also many graphs which do not possess proper interval colourings), and to establish upper and lower bounds on $\hat{t}(G)$ in terms of the graph diameter and the maximum degree.

## 2. Properties and results

In the analysis of improper interval colourings, the following observations (which are easy to see) will be useful:

Proposition 2.1. If a graph $G$ is improperly interval $k$-colourable with $k \geqslant 3$, then it is also improperly interval $k$-colourable in such a way that the colours 1 and $k$ are used exactly once.

Proposition 2.2. A graph $G$ is improperly interval l-colourable for each $1 \leqslant$ $l \leqslant \hat{t}(G)$.

First, we present an upper bound on $\hat{t}(G)$ in terms of the maximum degree and the diameter:

Lemma 2.3. For any connected graph $G$ with maximum degree $\Delta=\Delta(G)$ we have $\hat{t}(G) \leqslant 1+(\Delta-1)(\operatorname{diam}(G)+1)$.

Proof. Let $u v$ and $x y$ be edges coloured by 1 and $k$, respectively, in an improper interval colouring of $G$ using $\hat{t}(G)$ colours. Observe that in each such colouring, the colours of each two adjacent edges differ by at most $\Delta-1$. Now, take the shortest
path $P$ between the vertex sets $\{u, v\}$ and $\{x, y\}$. Then $P$ has the length at most $\operatorname{diam}(G)$; note, however, that the edges $u v$ and $x y$ need not belong to $P$. It follows that the number of colour changes from $u v$ to $x y$ along $P$ is at most $\operatorname{diam}(G)+1$, which implies the result.

Note that this lemma generalizes the result of [1] where the right hand side of the above inequality estimates $t(G)$ from above. Using the same arguments, we can prove an analogous inequality with respect to the diameter of the line graph $L(G)$ :

Lemma 2.4. For any connected graph $G$ with maximum degree $\Delta=\Delta(G)$ we have $\hat{t}(G) \leqslant 1+(\Delta-1)(\operatorname{diam}(L(G))$; the bound is sharp.

We also present strengthenings of two theorems from [1]:

Theorem 2.5. For each triangle-free graph $G$ on $n$ vertices, $\hat{t}(G) \leqslant n-1$; the bound is sharp.

Proof. We follow the same reasoning as in the proof of Theorem 1 from [1]; the difference is only in the estimate of the number of elements of the set $A(i)$ (see the original proof, page 38): we obtain that for an improper interval $t$-colouring of $G$ the inequality $|A(i)| \geqslant f\left(e_{i}\right)-f\left(e_{i+1}\right)-1, i=1, \ldots, k-1$, holds (instead of equality). Hence, the last argument of the original proof rephrases as

$$
\begin{aligned}
n & \geqslant k+1+\sum_{i=1}^{k-1}|A(i)| \geqslant k+1+\sum_{i=1}^{k-1}\left(f\left(e_{i}\right)-f\left(e_{i+1}\right)-1\right) \\
& =k+1+t-1-(k-1)=1+t
\end{aligned}
$$

implying $t \leqslant n-1$.
To show the sharpness of the bound, consider the graph of the path on $n$ vertices $P_{n}, n \geqslant 2$. It is easy to see that $\hat{t}\left(P_{n}\right)=n-1$.

Since the original proof of Proposition 4 of [1], page 39, does not require the considered interval colourings to be proper, we obtain the following theorem.

Theorem 2.6. For each graph $G$ on $n$ vertices, $\hat{t}(G) \leqslant 2 n-1$.
For the lower bound on $\hat{t}(G)$, we have the following estimate:

Theorem 2.7. For each graph $G, \hat{t}(G) \geqslant 1+\operatorname{diam}(L(G))$; the bound is sharp.

Proof. Consider the line graph $L(G)$ of $G$ and let $x$ be a vertex of maximum eccentricity in $L(G)$. Then colour the vertex $x$ with colour 1 and each vertex $y \in$ $V(L(G)), y \neq x$ with the colour equal to $1+\operatorname{dist}_{L(G)}(x, y)$. This vertex colouring of $L(G)$ induces an edge colouring of $G$. The way the colouring of the vertices of $L(G)$ was constructed gives that in $G$, the palette of each vertex consists either of two consecutive colours or of a single colour; thus, it is an improper interval colouring of $G$ having the highest colour equal to $\operatorname{diam}(L(G))+1$.

To show the sharpness of the lower bound, consider for an integer $k \geqslant 6$ the graph $D B_{k}$ obtained from a $k$-vertex path $x_{1} x_{2} \ldots x_{k}$ by adding new edges $x_{1} x_{3}$ and $x_{k-2} x_{k}$. Then it is easy to check that $\hat{t}\left(D B_{k}\right)=k-1$ and $\operatorname{diam}\left(L\left(D B_{k}\right)\right)=k-2$.

The difference between $t(G)$ and $\hat{t}(G)$ can be arbitrarily large. This can be seen on the graph $S N_{k}$ formed from a chain of $k$ copies of the graph $K_{4}^{-}$where both chain ends are closed with a different triangle, see Figure 1. It is easy to see that the graph $S N_{k}$ has a proper interval colouring; observe that in each proper interval colouring of $S N_{k}$, the difference of colours of two consecutive bridges incident with the same copy of $K_{4}^{-}$is 0 or 3 while it is possible to construct an improper colouring of $S N_{k}$ such that the colour difference on consecutive bridges is 4 . Thus, we obtain that $\hat{t}\left(S N_{k}\right)-t\left(S N_{k}\right) \geqslant k$. A similar construction can be used also for triangle-free graphs, where instead of copies of $K_{4}^{-}$, the 5 -cycle with pendant edges incident with two nonadjacent vertices is used: the difference of colours on bridges in a proper interval colouring is at most 3 whereas it is possible to assign the colours in such a way that the difference is 4 in an improper interval colouring, see Figure 2.

Figure 1. The graph $S N_{k}$ and its proper and improper interval colourings.
The construction generalizes to classes of graphs of arbitrarily large girth. Moreover, one can consider several other suitable configurations to show that the colour difference on two selected edges can be greater in an improper version of the colouring rather than in the proper one, and these configurations may be used to form other graphs (for example 2-connected) with arbitrarily large difference between $t(G)$ and $\hat{t}(G)$.

Figure 2. An analogous construction for triangle-free graphs.
There is no known significant upper bound on the difference $\hat{t}(G)-t(G)$ in terms of the number of vertices of $G$.

In the following, we establish the exact values and estimates of $\hat{t}(G)$ of graphs from several standard graph families.

Theorem 2.8. For an $n$-wheel $W_{n}$,

$$
\hat{t}\left(W_{n}\right)= \begin{cases}4 & \text { if } n=3 \\ n & \text { if } n \geqslant 4 .\end{cases}
$$

Proof. Suppose first that $n=3$. If $\hat{t}\left(W_{3}\right) \geqslant 5$, then the unique edge of $W_{3}$ which is not adjacent to the edge of maximum colour would have a colour at least 2 , so colour 1 is not used, a contradiction; on the other hand, an improper interval 4-colouring of $W_{3}$ is easy to find.

Now, let $n \geqslant 4$. An improper interval $n$-colouring of $W_{n}$ can be constructed in the following way: if $x$ is the centre of $W_{n}$ and $x_{1}, \ldots, x_{n}$ are its neighbours in counter clockwise order, assign to each edge $x_{i} x_{i+1}, 1 \leqslant i \leqslant\lceil n / 2\rceil$ colour $2 i-1$, to each edge $x_{i} x_{i+1},\lceil n / 2\rceil<i \leqslant n$ (indices taken modulo $n$ ) colour $2 n+4-2 i$, and to each edge $x x_{i}, i \notin\{1,\lceil n / 2\rceil+1\}$ the colour equal to the arithmetic mean of colours of edges $x_{i-1} x_{i}, x_{i} x_{i+1}$, whereas the edge $x x_{1}$ receives colour 1 and the edge $x x_{\lceil n / 2\rceil+1}$ receives colour $n$. It is easy to check that in this colour assignment, the palette of each vertex forms an integer interval (note that the palette of $x_{1}$ is $[1,2]$ and the palette of $x_{\lceil n / 2 t\rceil+1}$ is $\left.[n-1, n]\right)$. See Figure 3 for illustration.

Assume now that for some $n, \hat{t}\left(W_{n}\right) \geqslant n+1$. Consider first the case when $n$ is odd. Then at least one of colours 1 and $n+1$ is used at a rim edge of $W_{n}$ (otherwise the palette of the central vertex of $W_{n}$ would not form an integer interval). Since

Figure 3. The improper interval $n$-colouring of a wheel $W_{n}$ for $n=7$ and $n=8$.
replacing each colour $c$ by colour $n+2-c$ yields also an improper interval ( $n+1$ )colouring of $W_{n}$, we can suppose, without loss of generality, that colour 1 is used on a rim edge $u v$. Note that the colours of two adjacent rim edges can differ by at most 2 ; this means that two edges $y w, w z$ which are - taking into account the bidirectional distance on the rim-most distant from $u v$, have the colour at most $1+2(n-1) / 2=n$. Thus, colour $n+1$ has to appear at a spoke edge of $W_{n}$ and, repeating the above colour difference argument, we obtain that this spoke edge is incident with the vertex $w$. Due to the fact that in the considered improper interval colouring, colour 1 is unique, the edge $u v$ is adjacent with at least two edges coloured by 2 and at least one of them-say, $v q$-is a rim edge (otherwise again, the palette of the central vertex would not, an integer interval). Then the colour sequence of the rim path $P$ from $u v$ through $v q$ ending by one of the rim edges incident to $w$ is $1,2,4, \ldots, 2 i, 2(i+1), \ldots, n-1$; this implies that one of $y w$ and $w z$ has colour $n-1$ and the other one has colour $n$. Now, if we take the rim path $P^{\prime}$ starting at $u v$, but with the opposite direction to $P$, we get that its colour sequence is $1,3,5, \ldots, 2 i-1,2 i+1, \ldots, n$. But then colour $n$ does not appear at a spoke edge, hence, the palette of the central vertex is not an integer interval, a contradiction.

Consider now the case when $n$ is even. Rephrasing the above arguments, we can suppose that colour 1 is used on a rim edge $u v$. According to the possible position of colour $n+1$, we distinguish two cases:

Case 1: Colour $n+1$ is on a rim edge. Then the colour sequences of both rim paths starting at $u v$ are $1,3,5, \ldots, 2 i-1,2 i+1, \ldots, n+1$, which gives that colours of all spoke edges are even numbers, a contradiction.

Case 2: Colour $n+1$ is on a spoke edge $x w$. Let $y w$ and $w z$ be the rim edges adjacent to $x w$; without loss of generality, let $y w$ be closer to $u v$ than $w z$ to $u v$. Then the colour sequence of a rim path starting at $u v$ and ending at $y w$ is $1,3, \ldots, 2 i-1$, $2 i+1, \ldots, n-1$, which yields that $w z$ has colour $n$. By the same argument as for $n$ odd, colour 2 has to be used on a rim edge incident with $u v$, hence, the colour sequence of the rim path between $u v$ and $w z$ is $2,4, \ldots, 2 i, 2(i+1), \ldots, n$. But then again, colour $n$ is missing at spoke edges, a contradiction.

Note that by [3] only three wheels are proper interval colourable, namely $W_{3}, W_{6}$ and $W_{9}$.

Next, we present the exact value for a graph $Y_{n}=C_{n} \square K_{2}$, the graph of an $n$-sided prism.

Theorem 2.9. For an $n$-prism graph $Y_{n}$ with $n \geqslant 3, \hat{t}\left(Y_{n}\right)=n+2$.
Proof. Let $Y_{n}=C_{n} \square K_{2}$. In a plane drawing of $Y_{n}$, there are two $n$-gonal faces $x_{1}, x_{2}, \ldots, x_{n}$ and $y_{1}, y_{2}, \ldots, y_{n}$ interconnected by the edges $x_{i} y_{i}, i=1, \ldots, n$ (the side edges); the edges of type $x_{i} x_{i+1}$ or $y_{i} y_{i+1}(i=1, \ldots, n$, indices are modulo $n)$ will be called base edges in the sequel.

Figure 4. The improper interval $(n+2)$-colouring of a prism $Y_{n}$ for $n=7$ and $n=8$.
First, we show that there exists an improper interval colouring of graph $Y_{n}$ with $n+2$ colours. It can be constructed as follows: Assign the edge $x_{1} y_{1}$ colour 1, the edges $x_{1} x_{2}, y_{1} y_{2}$ colour 2 , the edges $x_{1} x_{n}, y_{1} y_{n}$ colour 3 and the edge $x_{\lceil n / 2\rceil+1} y_{\lceil n / 2\rceil+1}$ colour $n+2$. Now, assign edges $x_{i} y_{i}$ colour $2 i-1$ for $i=2, \ldots,\lceil n / 2\rceil$. Assign the remaining side edges $x_{i} y_{i}$ colour $2(n-i)+4$ for $i=n, \ldots,\lceil n / 2\rceil+2$. The colours of the remaining base edges are now determined unambiguously, see Figure 4 for illustration.

Now we prove that the colouring is optimal. Observe that $\operatorname{diam}\left(L\left(Y_{n}\right)\right)=$ $\lfloor n / 2\rfloor+1$, hence Lemma 2.4 gives an upper bound $\hat{t}\left(Y_{n}\right) \leqslant 2\lfloor n / 2\rfloor+3$. For $n$ odd this meets the lower bound.

Suppose that $n$ is even and there is an interval edge colouring of $Y_{n}$ with $n+3$ colours. From the proof of Lemma 2.4 we know that for any pair of edges in $G$ coloured with 1 and $n+3$, the corresponding vertices in $L(G)$ are at the distance $\operatorname{diam}(L(G))$. This is possible either for a pair of side edges $x_{i} y_{i}$ and $x_{j} y_{j}$ with $|i-j|=n / 2$, or for a pair of base edges $x_{i} x_{i+1}$ and $y_{j} y_{j+1}$ with $|i-j|=n / 2$. In both the cases all edges incident with the edge assigned colour 1 lie on some path of the optimal length between the edges assigned 1 and $n+3$, so all these edges have
to be assigned colour 3, which is a contradiction, since there is no colour 2 in the palettes of vertices incident with the edge assigned colour 1.

Finally, we discuss the improper interval colourings of complete graphs, which is of particular interest due to the ongoing intensive research in [9], [10].

Theorem 2.10. For a complete graph $K_{n}$ with $n \geqslant 5$, we have $\hat{t}\left(K_{n}\right) \leqslant 2 n-5$.
Proof. By contradiction. Assume that there exists a positive integer $n \geqslant 5$ such that $K_{n}$ is improperly interval $(2 n-4)$-colourable. Let $x y$ and $u v$ be edges coloured by 1 and $2 n-4$, respectively; note that $x y$ and $u v$ are not adjacent. Then the colour of $x u(x v, y u$ or $y v)$ is either $n-2$ or $n-1$. We claim that the palettes of both $x$ and $y$ contain each of colours $1, \ldots, n-1$ exactly once; similarly, the palettes of both $u$ and $v$ contain each of the colours $n-2, \ldots, 2 n-4$ exactly once: If both $x u$ and $x v$ had colour $n-2$, then palettes of $u$ and $v$ would contain each of colours $n-2, \ldots, 2 n-4$ exactly once, hence, $y u$ and $y v$ would have colour $n-1$, which is impossible.

Let $z$ be a vertex of $K_{n}$ such that $z x$ has colour 2 . Then the colour of the edge $z u$ is at least $n$ (because of $u$ ); note, however, that the difference of the highest and the lowest colour (which is colour 2) in the palette of $z$ is at most $n-2$, which means that the highest colour in the palette of $z$ is at most $n$. Therefore, the colour of $z u$ is equal to $n$. The same argument can be used for the edge $z v$, obtaining that its colour is also $n$. But then the palette of $z$ is not an integer interval, a contradiction.

Theorem 2.11. For each $n, \hat{t}\left(K_{n}\right)<\hat{t}\left(K_{n+1}\right)$.
Proof. Let $c$ be an improper interval $\hat{t}$-colouring of $K_{n}$ with $\hat{t}=\hat{t}(G)$, and let $w_{1}, \ldots, w_{n}$ be an ordering of vertices of $K_{n}$ such that $w_{1}$ is incident with an edge of colour $\hat{t}$. Now, add to $K_{n}$ a new vertex $u$ and for each $1<i \leqslant n$ add a new edge $u w_{i}$ coloured with colour $c\left(w_{1} w_{i}\right)+1$; the edge $u w_{1}$ will then be coloured with $\hat{t}+1$.

Theorem 2.12. For each $n, \hat{t}\left(K_{n+2}\right)-\hat{t}\left(K_{n}\right) \geqslant 3$.
Proof. Let $c$ be an improper interval $\hat{t}$-colouring of $K_{n}$ with $\hat{t}=\hat{t}(G)$, and let $w_{1}, \ldots, w_{n}$ be an ordering of vertices of $K_{n}$ such that $w_{1}$ and $w_{2}$ are endvertices of an edge of colour $\hat{t}$. Now, add to $K_{n}$ two new vertices $x, y$ and for each $3 \leqslant i \leqslant n$ add new edges $x w_{i}$ and $y w_{i}$ coloured with colour $c\left(w_{i} w_{1}\right)+1$ and new edges $x w_{1}$ and $y w_{2}$ coloured with $\hat{t}+1$. In addition, add new edges $y w_{1}$ and $x w_{2}$ coloured with $\hat{t}+2$ and the new edge $x y$ coloured with $\hat{t}+3$.

Theorem 2.13. For each $n, \hat{t}\left(K_{n}\right) \geqslant(7 n-17) / 4$.

Proof. We prove first that $\hat{t}\left(K_{4 k}\right) \geqslant 7 k-3$ for every $k \geqslant 1$. The general bound is then implied by Theorems 2.11 and 2.12 .

Let $n=4 k$ for $k \geqslant 1$, let $G=K_{n}$, and let $V(G)=\{0,1, \ldots, n-1\}$. We define a colouring of the edges of $G$ in the following manner: The colour of the edge joining vertices $4 i+r$ and $4 j+s$ with $0 \leqslant i<j \leqslant k$ and $r, s \in\{0,1,2,3\}$ is given in Table 1 , the colour of the edge joining vertices $4 i+r$ and $4 i+s$ with $0 \leqslant i \leqslant k$ and $0 \leqslant r<s \leqslant 3$ is given in Table 2. It is easy to observe that this is an (improper) interval colouring of $G$.

|  |  | $4 j$ | $4 j+1$ | $4 j+2$ |
| :--- | :--- | ---: | ---: | ---: |
| $4 j+3$ |  |  |  |  |
| $4 i$ | $3 i+4 j$ | $3 i+4 j+1$ | $3 i+4 j+2$ | $3 i+4 j+3$ |
| $4 i+1$ | $3 i+4 j+1$ | $3 i+4 j$ | $3 i+4 j+3$ | $3 i+4 j+2$ |
| $4 i+2$ | $3 i+4 j+2$ | $3 i+4 j+3$ | $3 i+4 j+1$ | $3 i+4 j+4$ |
| $4 i+3$ | $3 i+4 j+3$ | $3 i+4 j+2$ | $3 i+4 j+4$ | $3 i+4 j+1$ |

Table 1. The colouring of a complete graph on $n=4 k$ vertices: the colour of an edge joining vertices $4 i+r$ and $4 j+s$ with $0 \leqslant i<j \leqslant k$ and $r, s \in\{0,1,2,3\}$.

|  | $4 i$ | $4 i+1$ | $4 i+2$ | $4 i+3$ |
| :--- | :--- | :--- | :--- | :--- |
| $4 i$ |  | $7 i+1$ | $7 i+2$ | $7 i+3$ |
| $4 i+1$ |  |  | $7 i+3$ | $7 i+2$ |
| $4 i+2$ |  |  |  | $7 i+4$ |
| $4 i+3$ |  |  |  |  |

Table 2. The colouring of a complete graph on $n=4 k$ vertices: the colour of an edge joining vertices $4 i+r$ and $4 i+s$ with $0 \leqslant i \leqslant k$ and $0 \leqslant r<s \leqslant 3$.

Note that for proper interval colourings it is not known whether the sequence $\left\{t\left(K_{n}\right)\right\}_{n=1}^{\infty}$ is monotone; also, any value of $n$ for which $t\left(K_{n-1}\right)>t\left(K_{n}\right)$ yields that $\hat{t}\left(K_{n}\right) \geqslant t\left(K_{n}\right)+2$.

To conclude this part, we list the exact values of $\hat{t}\left(K_{n}\right)$ for some small values of $n$, see Table 3.

| $n$ | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| lower bound from Theorem 2.13 |  | 4 | 5 | 7 | 8 | 11 | 12 | 14 | 15 | 18 |  |
| $\hat{t}\left(K_{n}\right)$ | 1 | 2 | 4 | 5 | 7 | 8 | 11 | 12 | 14 | 16 | 18 |
| upper bound from Theorem 2.10 |  |  | 5 | 7 | 9 | 11 | 13 | 15 | 17 | 19 |  |

Table 3. Bound and exact values of $\hat{t}\left(K_{n}\right)$ for small values of $n$.
