Handwritten text, likely bleed-through from the reverse side of the page. The text is mostly illegible due to fading and blurring, but appears to be organized into several lines or paragraphs.

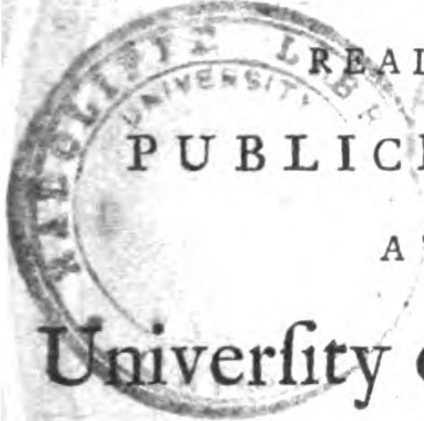

Printed for Stephen Austin at the Angel and Bible in S.^t Paul's Church.

The Usefulness of Mathematical Learning explained and demonstrated :

BEING

MATHEMATICAL
LECTURES

LREAD IN THE
PUBLIC SCHOOLS
AT THE
University of CAMBRIDGE.

By *ISAAC BARROW*, D. D. Professor
of the MATHEMATICS, and Master of
Trinity-College, &c.

To which is prefixed,

The ORATORICAL PREFACE of Our Learned
AUTHOR, spoke before the University on his
being elected *LUCASIAN* Professor of the
Mathematics.

Translated by the Rev^d. Mr. *JOHN KIRKBY*,
of *Egremond* in *Cumberland*.

THE

T H E

Prefatory ORATION.

SINCE some Respite has been given to the Hurry of your ordinary Employments, and the Tranquillity which in the mean Time is restored to your Affairs, has prepared your Minds and opened your Ears for the telling and hearing new Things ; if it may be acceptable to you, pray give your Attention, while I satisfy myself with imparting something strange, and not unlike a Prodigy. Fortune has smiled of late : Why are ye disquieted ? Do we gaze upon the dire Comet that now shews itself, as the Harbinger of the Mischances that daily encrease upon us, or upon the Armies of Fanaticks bent against the Will of Heaven ? Rather let us turn our Eyes upon a new but beneficial Star, sparkling with a true as well as auspicious Lustre, never the like of which for many Years past has appeared above the Horizon of this University ; to compute whose Magnitude, explain its Motions, and preface its Events, I am come hither, not as a vain Astrologer.

Would you have me speak more plainly ? No Body then, who has either turned his Eyes upon the calamitous State of Literature, or not been altogether deaf to the frequent Complaints of learned Men, can be ignorant how unequally the present Age behaves against the one, how maliciously and ungratefully towards the other. Wherefore we may the more wonder that a noble *Mecænas* has at last

appeared, a *Mecænas* not in Name, but in Fact; not one who has made a shew of bare Favour towards Learning, but who has spent much real Labour in it; not who has embraced it with a good Will only, but who has obliged it with a Munificent Hand; by regarding its present Melancholy State, wiping the Stain of Infamy from off the Age, inspiring Vigour into these languishing Studies, and clearing the Path of doing Benefits which lay covered through long disuse without the least Sign of Footsteps. To declare the Praises and publish the Virtues of which Man, I wish I had Words suitable to such great Merits and Eloquence equal to the Matter, and that it were not as difficult to speak worthily upon such an illustrious Argument, as it is unpardonable, that it should be altogether passed by in Silence. However since publick Gratitude, and especially the Reason of my own private Office, requires it, though I have not the Faculty to grace the Memory of our Benefactor with a suitable Eulogy, yet I will shew my good Will to do it, at least in some, though imperfect and disagreeable Manner.

Henry Lucas, then, was the Person (to whose great Name you of this University owe the highest Reverence and Esteem) *Lucas*, I say, a Name at once thundering forth the Prowess of *Mars*, and breathing the Wisdom of *Minerva*; which will fill both Pages of History with the Glories of War and Peace, and be equally celebrated by Posterity, for the Examples of Heroic Fortitude, and God-like Munificence. *Henry Lucas*, a Man much to be honoured for the Dignity of his Descent, as being related to very noble Families by the nearest Kindred of Blood; but the Greatness of his Mind rather detracted from the Nobleness of his Stock, and darkened the Splendor of his Parentage with the Excellence of his Virtues. He was born to
a moderate

a moderate Fortune, which by a thriving Injustice, the Importunity of a litigious Court, and the Unlawfulness of the Law bereft him of, while an Orphan ; left either his Ability of living honourably himself, or the glorious Faculty of benefiting others, should be imputed to a foolish Fortune, rather than to a laudable Industry. For to be possessed of Riches transmitted from Parents is a Matter of pure Felicity, but to acquire them honourably of ones self is perfectly Praise-worthy : to impart of the Things a Man has received has the Appearance of just Restitution ; but courteously to bestow the Fruits of his own Labour deservedly obtains the Title of Liberality. It is from hence the Case reaps the greatest Glory, from hence the Virtue becomes compleat. Such is our Benefactor, the Maker of his own Fortune, the Heir of his own Virtue, the Issue of his own private Industry : He struggled from Poverty to Abundance, from a low Estate to a Degree of Eminence. Perhaps you will enquire by what Means, or on what Helps he did rely. Was it by proceeding in Rapines, by formenting Quarrels, by trucking Commodities, or practising unlawful Gain? None of these, but by the most harmless Method, the most approved Arts and sacred Instruments, whereby Nature has instructed Men to keep off the Inconveniences of Life ; by Politeness of Judgment, Eloquence of Speech, and Probity of Manners. Being entered into the most honourable College of *St. John* (which among all that vast Number of famous Men it has afforded to the Church, and very many to the Commonwealth, and I think has not brought up a Scholar more profitable to the University ;) I say, being entered into this fruitful Seminary, he profited so well, so cultivated his Understanding with the liberal Arts, and seasoned his Mind with the Principles of Virtue ; that when there was no

Office

a grateful Return for those Benefits, and oblige her with mutual good Offices? For to be appointed once or twice to the supreme Court of the Kingdom in the Name of the University, there to plead the Cause, undertake the Defence, and sustain the Part of a learned Community; to represent your Body, *i. e.* the very Body of Learning itself; and to be approved, elected, and preferred before other worthy Competitors by your most grave Judgment; is this a slight Honour? Nay is it not to be esteemed beyond any Price, and preferred above all proud Titles? And I heartily wish your Judgments may be always so fortunately aimed, your Benefits so rightly placed, that they whose Education has raised them to a more exalted Degree, and who have had a like Testimony of your Benevolence, may become the same way minded to you: And thus the liberal Sciences would not be so impoverished, so shareless of Honour; nor would our Studies languish being destitute not only of due Rewards, but also of necessary Supports. He indeed alone for many Years past has protected Letters from Injury, he has rescued the Sciences from Contempt, delivered them from Want, assisted them with his Endeavours, and enlarged them with his Interest. For in these wicked and unhappy Times, when a covetous Barbarity gaped after the Profits of the University, imposing Burthens upon all, and every where exacting the most unreasonable Taxes; stoutly defended your Cause and maintained your Immunities; he strenuously exerted all his Power, and effected much, what through Advice, what through Persuasion, that the Gown might not be made tributary to the Cloth; that the Fury of *Mars* might not prey upon the Property of *Minerva*; that the Wealth dedicated to the Nurture of the liberal Arts might not be perverted to maintain the worst of Tyrants, and to promote the Enterprizes of
of

of wicked Men. Thus he at that Time made himself your Shield against a dangerous Indolence, that he might afterwards become your Sword against Ignorance; he took from you a pernicious Loss, that he might enrich you with an advantageous Gain. For when he perceived himself to have arrived at the last Stage of his mortal Course, that he might at least survive for your Benefit, and not cease to be profitable to you, even when he ceased to live; he began to consider with himself and advise with his Friends, by what Means he might best suit your Studies; resolving to strengthen that Part with suitable Helps, where you were weakest, to apply fit Remedies to your Wounds, supply your Wants and retrieve your Losses.

While he had an Eye upon all Things, the Subject of *Mathematical Learning* offered itself as most worthy of his Beneficence: Which, being recommended by a singular advantageous Profit, joined with an entertaining Pleasure, by its peculiar Difficulty that required no small Assistance, the exceeding Care with which it was cultivated among the ancient Philosophers, the extraordinary Applause it received among Men of all Ages, and especially the surprizing Honours paid to it by the present Age, I know not whether it is more to be accounted a Matter of Wonder, or of Grief, that it had hitherto obtained no Place, no assigned Reward, no allowed Privilege in the University, the fruitful Mother of all Disciplines, and benign Nurse of all Studies. Being desirous to remove so great a Dishonour, and restore this neglected Science, he lent to his helping Hand, so that the Profession of *Mathematics* was introduced by his Management, and endowed with a liberal Stipend from his Substance. Moreover when the *Lambeth Books* taken from your Library had given you so grievous a Wound, he in Part healed, at least very
‡much

much mitigated, it, by substituting his own; indeed a Library less stately and magnificent, but equally choice and precious; a remarkable Monument of his own Learning, and a Help to yours. Which Benefits, since they cannot be amplified with Words, nor illustrated with Colours, and since it is altogether the same to relate them simply, as to celebrate them at large, I will rather commit them to you to be cultivated with a grateful Remembrance, than be violated by me with a rude Encomium. However we may briefly take Notice by the by, that though many have testified their good Affection to several Colleges, and contributed large Gifts (the Mother, as is usually done, being neglected that the Daughters may have better Treatment) yet hitherto no Son has been equally dutiful, no Scholar equally grateful, no Patron equally liberal to the University in general: Their Gifts were of as much narrower a Mind, as much slighter a Merit than his, as the Sun in the Firmament outshines the Candle in the House; or as it is more noble to diffuse a beneficial Influence upon all, than only to derive it upon a few. In like manner though others might afford greater Gifts, yet our Benefactor dispensed his more prudently, if that was the most fitting Season, when your too long neglected Affairs required a conspicuous Favour, and when the melancholy Condition of Letters implored a powerful Assistance to Uses necessary in the highest Degree; the want whereof it is hard to say, whether it was more dishonourable, or more detrimental to you. Lastly others have deserved very much of you for the Benefits they have done, but no Body so much for the Examples they have shewn. Those cried up Learning while it was in Vogue, according to the Disposition of the Times, complying with the Manners of the Age they lived in; but he opposing the contrary Genius of his Age
durst

durst favour Learning while it struggled with Envy, and was exposed to Reproach, and therefore is worthy to be had in the greater Esteem: Those adjoined themselves Companions, or rather Foot-men, to them that travelled in the beaten Path; he walked through an impervious Solitude, a Guide to himself, a Companion to none: Those cherished the Hopes of Studies while quick and lively; he raised them when fallen, restored them when depressed, and revived them when almost buried: Those in some measure sustained, or a little promoted the Fame of their own Times, while flourishing; but he not only very much honoured the Age he lived in, but delivered it from the greatest Infamy. Lastly, those obtained a vulgar Praise from such vulgar Benefits; but our Benefactor acquired, nay merited, a singular Glory from a singular Beneficence. He indeed far outwent the Merits of them that went before him, and has snatched away the Palm from them that are to follow him: We are beholden to him for what he has done himself, and hereafter shall be beholden to him, for what others shall do in Imitation of him; to whom he has before afforded a happy Omen, carried a shining Light, and shewn them an open way to promote Learning under his Patronage; that none hereafter may be ashamed of Liberality bestowed upon Literature, but that all ought rather to be ashamed of not following the Authority of such a Man, of not walking in the Footsteps of so great a Guide.

But I am carried unawares too far into the Sea of a boundless Oration, and do plainly perceive how very easy it is for one who is engaged in an Argument so noble, so splendid, so generous, to say more than enough: Therefore humbly begging your Pardon, I will contract my Discourse, yet so (most worthy Man) as rather to cover thy
private

private Praises with a modest Silence, than disgrace them with an unseasonable Publication. Thy extraordinary Piety towards God, Regard towards Friends, Benignity to all; thy unspotted Candor of Mind, blameless Probity of Manners, singular Courtesy in Conversation, Skilfulness in Action, Perspicuity of Judgment and Eloquence of Speech; thy Faithfulness in performing Obligations, Equity in Deeds, Modesty in Words, and Constancy in Purpose; finally thy sincere Love of Truth, ardent Study after Knowledge, generous Disposition, consummate Learning, and thy innumerable other God-like Virtues of Mind, noble Endowments of Understanding, and remarkable Actions of Life; these Things indeed I have received, as Rays conveyed in a Course not direct but broken and weakened with the Interposition of a thicker Medium; I have not known them by my own Experience, but relying upon the Credit of others have had them from Fame alone; yet a Fame certain and undoubted, supported by the united Suffrages of many good and wise Men; so that if I attempted to go through with this Subject, it would be like a blind Man's undertaking to paint the brightest Lustre, or a deaf Man to sing the sweetest Melody. O that I could behold thy living Countenance encompassed round with so delightful a Splendor, that I could contemplate thy Demeanor mingled with that gentle Severity, could taste thy Speeches seasoned with such a sweet Salubrity, and draw some few Drops from that inexhaustible Sea of Eloquence: Perhaps a Breast impregnated with thy Breathings might conceive something like thee, and a Mouth moistened with thy Nectar might express something worthy of thee. But I think it better for me not at all to meddle with so great Virtues, than do them Injury by handling them unworthily, or fully them with an unpolite Speech, There

There only remains one Commendation more (and that not to be reckoned among the last) which I ought in no Reason to pass by; I mean the Commendation of a most happy Prudence shewn in chusing and deputing those to whom he designed to commend the chief Care of executing his Will, or rather of dispensing his Charity. For since Things the best designed, either by the base Dishonesty, slothful Negligence, or stupid Folly of those to whom they are committed, do often fail and miscarry of their hoped for Success; he took abundant Care that this might not be his own Lot, and appointed two Men for his Administrators of sincere Honesty, unwearied Diligence, and approved Prudence; whose Names it would be the most unpardonable Thing in me not to mention with all grateful Remembrance, their great Regard towards you, and singular Humanity to myself being sufficiently experienced. The one who is perhaps not so well known (yet worthy to be known and honoured by all) is that most excellent and accomplished Person, *Robert Raworth*, a Man singularly discreet and prudent, who to his remarkable Skill in Law adjoined an equal Love of Justice, to his great Experience an uncommon Integrity of Mind; especially wonderful and happy in this, that while he manages all Things according to the strict Rules of Equity, never preferring the Pleasure of hearing well before the Inclination of doing well, yet has been able to obtain the Opinion of the best of Men among all, and to preserve an unspotted Character together with a sound Conscience: A Man perfectly just, and unshaken in that Situation, wherein Reason has affixed him, of a worthy Behaviour, a free and ingenuous Disposition, involved in no Cloud, covered over with no Daubing, quick and sagacious in discerning the Importance of Things, mature

a

and

and circumspect in taking Advice, constant and steady in retaining his Purpose ; one who attempts nothing rashly, nor easily suffers himself to be removed from a promising Undertaking. Lastly a Man in whom the greatest Trust may be safely reposed, and weightiest Affairs aptly committed, having behaved himself in this Province so faithfully, dexterously and wisely, that not only I myself, with all that shall hereafter succeed me in this Office, but also the whole University, and all good Literature shall owe him immortal Thanks. But the other, *Thomas Buck*, is perfectly known to every one of you from the honourable Place which he has sustained among you for so many Years, being sufficiently recommended by his Virtues, and highly to be revered for his excellent Merits towards you: The very same whose august Appearance and venerable Dignity of Countenance is daily seen with your Eyes, whose most courteous Civility you always perceive, and whose active, trusty and fortunate Endeavours in managing your most important Affairs, vindicating your Honour and promoting your Interest, you have so often experienced. A Man endowed in no mean Degree in all the Parts of good Literature, who yields the Preheminence to none in Prudence and Faithfulness (Things approved and demonstrated in him, after a most remarkable Manner) and leaves most, I had almost said all, Mortals a long Space behind him in a laudable Industry. It would be difficult, nay altogether impossible for me to express what Labours he has undergone, what Troubles he has endured, how much Pains he has taken for your Sakes, or that my Diligence in saying should come up to his Diligence in doing. I was a Witness, I say a Witness, as far as Admiration permitted, how much he provided for your Honour, how serviceable he was to your Interest,

while he pushed forward your Business of Printing at the Expence of his own Health and Substance, the Praise of which will endure to the most distant Posterity imprinted on shining Characters, and consecrated to Eternity with the sacred Writings themselves, whose Value and Excellence he has in some sort advanced. But while I am speaking of this, I cannot observe without great Astonishment, a Man grown up in Years, and in a bad State of Health, to have been able if he was willing, or willing if he was able, to use such Vigilance over the Affairs of others, as perhaps none else, even in the Prime of his Strength and Vigour, would have used over his own. So great an Ardour inflamed him of meriting well of you, such a Desire of finishing the great Work he had begun, that the Strength of his Body and Vigour of his Mind, seemed to encrease with his Years, and the nearer he approached to the End of his Life the more vigorously he seemed to be carried. But why do I commemorate his Diligence in this Performance, rather than mention the unwearied Study wherewith he undertook it, and his great Benevolence shewn towards you? For indeed you owe the first Fruits of this huge Benefit, in Part to him: our great Benefactor being excited by his Admonition, persuaded by his Advice, and drawn by his Exhortation, both to institute this Mathematical Profession, and to endow and adorn your Library with a most choice Treasure of Books. For is not he to be accounted the Author of a Benefit who hath gained and as it were given you the Benefactor himself, who hath as well profited for you out of another Person's Wealth, as out of his own Wisdom, his own Good-Will; and who hath derived upon your Grounds the overflowing Streams of another's Munificence? Without whom indeed it had not been, it could not be to Day that I could congratulate you upon the Ac-

cess of such a Help to your Studies, such an Ornament to the University, such an Example to the Age: Here my Tongue falters, my Invention fails, and my Mind ceases to furnish me with Words in any wise suitable to so vast a Benefit, the Greatness of which is easier to be conceived than expressed. I will therefore forbear attempting so insuperable a Difficulty, only give me leave to declare this one Thing, that the last Gentleman's remarkable Kindness towards me has merited a far greater Testimony of Gratitude.

What then can be said of these two worthy Persons appointed for this Office? Did they violate the Trust committed to them, or delude the Hope conceived of them? Were they too intent upon their own private Advantage, or did they delay the hoped for Benefit for many Years? Nay, did they permit even one Year to pass, without being a Witness of the Discharge of their Trust, of the Answer of their Appointment? They apply themselves quickly to the Work, take speedy Care of procuring you Books, purchase Lands for the Professor's Salary, prescribe Laws for determining the Office; in sum, leave nothing undone to prevent the Corruption of the Meaning of so great a Benefit by Delays; so that your Hope was even anticipated by its Expedition, and you scarcely sooner knew what you had to expect, than you perceived yourselves in the actual Possession: I said they prescribed Laws, but I will not presume to declare your Judgment of them, nor arrogate so weighty a Censure to myself, how just they are in themselves, how profitable to your Studies, and how suitable to your Circumstances. At least I dare affirm this for certain, that of several able and unprejudiced Judges, Men of Worth and Honour who have seen them (I speak within compass, for a great many saw them who were no less eminent

nent for their high Dignity than their remarkable Wisdom) the most approved well of them; and their Number was not small that judged them worthy of all Commendations, however, so far worthy, that when seen, no Body opposed their Establishment by the King's Authority. And having thus effectually performed their Parts, they were not yet content to proceed no farther, but such was their Good-Will, that in some Measure they out-went the Limits of their Power, obtaining to this Place a good many Privileges farther from the King's Clemency, which themselves could not bring about, such as were either very profitable or altogether necessary: By which Means, whosoever shall hereafter obtain the Office of this Profession will be obliged in Gratitude to acknowledge and confess them its second Founders, at least principal Fautors. I will venture to speak no farther of those Reverend Heads of Colleges, by whose Advice this Affair was chiefly carried on, who are as much superior to me in Judgment and Eloquence, as in Years and Dignity; I only beg leave to make this one Remark, that as to what relates to the common Good, they have acted wisely and moderately, as it became such Men; but all of them have laid no small Obligations upon me, and above all I am in the highest Degree bound to the two most worthy Vice-Chancellors of the last and the present Year, for their singular Kindness and Benevolence towards me.

Thus the Debt of a grateful Remembrance being in some sort discharged, it will perhaps be expected that I should declare some out of the way Things, as particularly to shew what Reason induced me to desert my former Office for undertaking a new one, which it may be will make me look in the Eyes of some, as a Man of a wavering or unconstant Disposition, too negligent of my own

Credit, and carelefs of yours : Which Perfons, if any fuch there are, would do better to moderate the Acrimony of their Judgment with a more deliberate Advice, and not rashly meafure the State of another Perfon's Mind by their own Meafure. The firmeft Rocks do now and then bear the Surges of contrary Tides, and the moft constant Men are oftentimes moved with the various Changes of Things. As to what belongs to the Matter ; I who upon Constraint had engaged my felf in the Province of Greek Profeflor, then defireable to none by reafon of the fmall or even no Reward for the vaft Labour attending it, when I conjectured there were many both very willing to undertake and able to difcharge that Office, as being for their Intereft fo to do, I conceived there was nothing to hinder me from entirely following my own Inclination, when it was no Inconvenience to you, and from changing a heavy Labour with a very light Gain, by withdrawing myfelf from the Drudgery of *Grammar* to the more defireable Exercife of *Mathematics*. For though I was never wholly averfe to *Philology*, yet not to diffeemble, I was always more deeply in Love with *Philofophy* ; tho' I did not morofely defpife the sportive Diverfion about Words, yet I had a more hearty Inclination for the ferious Enquiry into Things ; I am not impatient of all kind of Labour, yet I am more defirous of a moderate Eafe ; I would fo far refrain from all Injury towards others, as to preferve my own Freedom over myfelf : In fhort, though I engaged myfelf to be moft obedient to your Pleafure, and moft mindful of your Authority ; yet did I never altogether renounce my Liberty : I did not enslave myfelf to Grammar Learning, nor fuffered my Ears to be bored through with the Languages, fo as to make it ever after unlawful for me to lay hold on an honeft Opportunity of deliver-
ing

ing myself; much less to disoblige my Friends, while they invited me to an Office indeed less honourable, but much more convenient, more acceptable to my Inclination, and which abounds with much more Freedom and Leisure. What needs more? I used my own Right and did not invade that of others; I left my own Profession, and did not thrust others out of theirs; I stripped myself of an Honour beyond my Desert, without degrading any one from his; much less did I seek to dishonour you, who are most beloved and revered by me; for whom I have always had the deepest Affection and most profound Esteem, and for whose Honour, if any one, surely I, did ever according to my small Ability shew myself the most obsequious, the most respectful, with Heart and Hand, with Word and Deed. Nor did I ever in the least depart from your Conversation, but when driven by some just Necessity, when constrained by hard need. No Device could compel, no Condition entice me from you, or make me altogether desert your Camp; nor did I ever fight under any other Colours, but your own. But I have not indeed so much forsaken your Confines as enlarged your Jurisdiction, I have not dishonoured your Name, but have extended it; nor do I seem to be carried so much by my own Head, as by a certain Fate careful and apprehensive of your future Advantage; that the Prelude I am now making to the Exercise I am about to enter upon, in this celebrated Circus, might serve also in some other more obscure Place. Whosoever then ungenerously reproaches me for this, as a faithless Deserter, or fugitive Servant, let him look what just and likely Reasons he has for so doing.

However I cannot but joyfully congratulate myself, that after having escaped so many Errors, been delivered from so many Disquietudes, experienced

So many Changes ; I have at length arrived at this still Port, and am repos'd in so safe a Station. For nothing could ever have happened more agreeable to my Wishes, than to be placed in the Bosom of our gracious Mother the University, which abounds with all Manner of innocent Delights ; even in your Society (consisting of Men endowed with the most ingenuous Disposition, sincere Affection, sublime Understanding, and unparallel'd Learning) which in my Opinion is to be envied by Kings themselves ; in the most beautiful Palace of the Muses, the most sacred Temple of Virtue, the most noble School of Wisdom, and illustrious Theatre of great Examples : Here to cultivate my Understanding, form my Manners, compose my Affections, and learn the Liberal Sciences along with you (being bound to you in a sufficiently honourable and easy Servitude, and enjoying a Condition by no means to be despis'd) is what, might I have my free Choice, I would a hundred Times sooner always chuse, than to live in the Poms of a Court, the Tumults of a City, or Solitudes of a Country ; did I fare ever so delicately, abound with the greatest Plenty, flow with all kind of bodily Pleasures, and were honoured with the highest Titles. Which Happiness granted me by the singular Kindness of a benign Providence, favourably regarding my Affairs while distressed in the highest Degree by these late Calamities, I look upon with that humble Reverence and pious Devotion of Mind, which is meet towards the Divine Majesty. And I also do gratefully acknowledge and embrace the Benevolence of good Men given me of their own most free Choice, without the least Entreaty or Solicitation of mine ; to whom, because I am not able to make any suitable Return, I will however do what in me lies in the Discharge of my Office, that they may neither re-
pent

pent of their Benefits conferred upon me, nor be ashamed of their Sentiments conceived of me. Which I do not speak, as if I were insensible of my own Meanness, or did arrogate any Thing to myself (for I openly confess that Weakness and Unworthiness, which I inwardly perceive) but to be a Spur to my Diligence, a Support to my tottering Understanding, that I despair not of supplying what is wanting in me with Industry, and recompensing my Inability with Care. But from you, who are liberally educated, I hope for, nay I promise to myself every Thing worthy your Candor and Humanity; nor do I in the least doubt, but as you have hitherto favoured me with your good Wishes, you will also now receive me with Kindness; being not unmindful of the Good-Will which I have shewn heretofore of recalling these Mathematical Studies from their Exile, and bringing them out of Darkness into Light.

And if, while I was a private Person nor otherwise obliged, being enamoured only with the Loveliness of the Thing, I shewed such hearty Desires and Endeavours to have these Sciences in the highest Degree recommended to you; it cannot now be doubted but by Reason of my publick Office, and more solemn Engagement, I will more diligently apply myself to their Promotion according to my slender Ability; since what was then an Inclination becomes now a Duty. But what the Laws do strictly require of me, that I have always shewed the greatest Readiness to perform, so that I did not only willingly admit, but earnestly invited you of my own Accord, to familiar Meetings, so that I not only once or twice every Week opened the Doors of my private Chamber, but daily publish'd the inward Secrets of my Heart, and unfolded my Breast to all Comers.

If it be then your Pleasure, ye Lovers of Study, come always ; be not restrained through any Fear, or retarded by too much Modesty, what you may do by your Right, you shall make me do willingly, nay gladly and joyfully. Ask your Questions, make your Enquiries, bid and command ; you shall neither find me averse nor refractory to your Commands, but officious and obedient. If you meet with any Obstacles or Difficulties, or are retarded with any Doubts while you are walking in the cumbersome Road of this Study of *Mathematics*, I beg you to impart them, and I shall endeavour to remove every Hindrance out of your Way to the best of my Knowledge and Ability. But if nothing else can compel you to apply yourselves vigorously to these Disciplines, and labour diligently in this Exercise, at least that Spur of noble Minds, the Thirst of following all great Examples, which always sinks deep into generous Dispositions, should the more strongly provoke and enflame you.

For to pass by those Ancients, the wonderful *Pythagoras*, the sagacious *Democritus*, the divine *Plato*, the most subtle and very learned *Aristotle*, Men whom every Age has hitherto acknowledged and deservedly honoured, as the greatest Philosophers, the Ring-leaders of Arts ; in whose Judgments how much these Studies were esteemed, is abundantly proclaimed in History and confirmed by their famous Monuments, which are every where interspersed and bespangled with Mathematical Reasonings and Examples, as with so many Stars ; and consequently any one not in some Degree conversant in these Studies will in vain expect to understand, or unlock their hidden Meanings, without the Help of a Mathematical Key : For who can play well on *Aristotle's* Instrument but with a Mathematical Quill ; or not be altogether deaf to the Lessons of natural *Philosophy*, while ignorant

rant of *Geometry*? Who void of (*Geometry* shall I say, or) *Arithmetic* can apprehend *Plato's Socrates* lisp- ing with Children concerning Square Numbers; or can conceive *Plato* himself treating not only of the Universe, but the Polity of Commonwealths regulated by the Laws of *Geometry*, and formed according to a Mathematical Plan? Nor to mention those Moderns resembling and nearly equalling the Ancients in Sagacity, viz. *Galileus*, *Gassendus*, *Gilbertus*, *Mercennus*, *Cartesius*, and such others of the present Age as were famous for having extended the Circuits of Natural Science beyond its ancient Bounds, depending only on the Mathematics; the Sight of whose Writings every where shining with the Rays of Geometrical Diagrams, the Unskilful in these Things are afraid of, as so many Owls at the bright Splendor of the Sun: Let us rather take a View of these Sciences, such as this Day they are presented to you, dignified in the Robes of Nobles, glorying in the Titles of Princes, and sitting upon the Thrones of Kings themselves: All whom it would yet be unmannerly to compare, and most unjust to prefer to you, in any Kind of ingenious Literature: Especially since you cannot merit the Name or sustain the Dignity of an University upon any other Account, than by preserving to yourselves a Knowledge more than common in all Kinds of Science becoming a generous Mind; and by taking away every Occasion of Calumny from all who either envy your Happiness, or emulate your Fame; not spending your Time like Infants in learning the Languages, nor neglecting the Care of searching after Truth for digging up foolish Fables out of the Rubbish of obsolete Antiquity; not affecting the vain Trappings of Words, and the Delusions of a painted Speech, while the Nature of Things lies unregarded, and the Use of plain Reason is set aside;

not

not lastly abusing your Leisure, playing away your Time, and miserably wresting and torturing your Wits with sophistical Trifles and empty Jargon, engaging yourselves in barren Disputes, insisting upon uncertain Conjectures, and venting of doubtful Opinions.

These Reproaches (which I confess are thrown upon you by way of Banter and without Cause) you may either easily wipe off, or entirely avoid, by only applying yourselves to the Study of the *Mathematics* with that Diligence which is requisite: The *Mathematics*, I say, which effectually exercises, not vainly deludes nor vexatiously torments studious Minds with obscure Subtilties, perplexed Difficulties, or contentious Disquisitions; which overcomes without Opposition, triumphs without Pomp, compels without Force, and rules absolutely without the Loss of Liberty; which does not privately over-reach a weak Faith, but openly assaults an armed Reason, obtains a total Victory, and puts on inevitable Chains; whose Words are so many Oracles, and Works as many Miracles; which blabs out nothing rashly, nor designs any Thing from the Purpose, but plainly demonstrates and readily performs all Things within its Verge; which obtrudes no false Shadows of Science, but the very Science itself, the Mind firmly adhering to it, as soon as possessed of it, and can never after desert it of its own Accord, or be deprived of it by any Force of others: Lastly the Mathematics, which depends upon Principles clear to the Mind, and agreeable to Experience; which draws certain Conclusions, instructs by profitable Rules, unfolds pleasant Questions; and produces wonderful Effects; which is the fruitful Parent of, I had almost said all, Arts, the unshaken Foundation of Sciences, and the plentiful Fountain of Advantage to Human Affairs. In which last Respect, we may be said

to receive from the *Mathematics*, the principal Delights of Life, Securities of Health, Increase of Fortune, and Conveniences of Labour : That we dwell elegantly and commodiously, build decent Houses for ourselves, erect stately Temples to God, and leave wonderful Monuments to Posterity : That we are protected by those Rampires from the Incursions of the Enemy ; rightly use Arms, skilfully range an Army, and manage War by Art, and not by the Madness of wild Beasts : That we have safe Traffick through the deceitful Billows, pass in a direct Road through the tractless Ways of the Sea, and come to the designed Ports by the uncertain Impulse of the Winds : That we rightly cast up our Accounts, do Business expeditiously, dispose, tabulate, and calculate scattered Ranks of Numbers, and easily compute them, though expressive of huge Heaps of Sand, nay immense Hills of Atoms : That we make pacifick Separations of the Bounds of Lands, examine the Moments of Weights in an equal Balance, and distribute every one his own by a just Measure : That with a light Touch we thrust forward vast Bodies which way we will, and stop a huge Resistance with a very small Force : That we accurately delineate the Face of this Earthly Orb, and subject the Œconomy of the Universe to our Sight : That we aptly digest the flowing Series of Time, distinguish what is acted by due Intervals, rightly account and discern the various Returns of the Seasons, the stated Periods of Years and Months, the alternate Increments of Days and Nights, the doubtful Limits of Light and Shadow, and the exact Differences of Hours and Minutes : That we derive the subtle Virtue of the Solar Rays to our Uses, infinitely extend the Sphere of Sight, enlarge the near Appearances of Things, bring to Hand Things remote, discover Things hidden, search

Nature out of her Concealments, and unfold her dark Mysteries : That we delight our Eyes with beautiful Images, cunningly imitate the Devices and portray the Works of Nature ; imitate did I say ? nay excel, while we form to ourselves Things not in being, exhibit Things absent, and represent Things past : That we recreate our Minds and delight our Ears with melodious Sounds, attemperate the inconstant Undulations of the Air to musical Tunes, add a pleasant Voice to a senseless Log and draw a sweet Eloquence from a rigid Metal ; celebrate our Maker with an harmonious Praise, and not unaptly imitate the blessed Choirs of Heaven : That we approach and examine the inaccessible Seats of the Clouds, the distant Tracts of Land, unfrequented Paths of the Sea ; lofty Tops of the Mountains, low Bottoms of the Valleys, and deep Gulphs of the Ocean : That in Heart we advance to the Saints themselves above, yea draw them to us, scale the ethereal Towers, freely range through the celestial Fields, measure the Magnitudes, and determine the Interstices of the Stars, prescribe inviolable Laws to the Heavens themselves, and confine the wandering Circuits of the Stars within strict Bounds : Lastly, that we comprehend the huge Fabrick of the Universe, admire and contemplate the wonderful Beauty of the Divine Workmanship, and so learn the incredible Force and Sagacity of our own Minds, by certain Experiments, as to acknowledge the Blessings of Heaven with a pious Affection.

I omit the advantageous Spur to our Reason which accrues from this Mathematical Exercise, both effectually to turn aside the Strokes of true Arguments, and warily decline the Blows of false ones ; to dispute strenuously as well as judge solidly with a Readiness of Invention, a Justness of Method, and Clearness of Expression.

In

In like manner these Disciplines serve to inure and corroborate the Mind to a constant Diligence in Study, to undergo the Trouble of an attentive Meditation, and cheerfully contend with such Difficulties as lie in the Way. They wholly deliver us from a credulous Simplicity, most strongly fortify us against the Vanity of Scepticism, effectually restrain us from a rash Presumption, most easily incline us to a due Assent, perfectly subject us to the Government of right Reason, and inspire us with Resolution to wrestle against the unjust Tyranny of false Prejudices. If the Fancy be unstable and fluctuating it is as it were poized by this Ballast, and steadied by this Anchor; if the Wit be blunt it is sharpened upon this Whetstone; if luxuriant it is pared by this Knife; if headstrong it is restrained by this Bridle; and if dull it is roused by this Spur. The Steps are guided by no Lamp more clearly through the dark Mazes of Nature, by no Thread more surely through the intricate Turnings of the Labyrinths of Philosophy; nor lastly is the Bottom of Truth sounded more happily by any other Line. I will not mention with how plentiful a Stock of Knowledge the Mind is furnished from these, with what wholesome Food it is nourished, and what sincere Pleasure it enjoys. But if I speak farther, I shall neither be the only Person, nor the first, who affirms it; that while the Mind is abstracted and elevated from sensible Matter, distinctly views pure Forms, conceives the Beauty of Ideas, and investigates the Harmony of Proportions; the Manners themselves are sensibly corrected and improved, the Affections composed and rectified, the Fancy calmed and settled, and the Understanding raised and excited to more divine Contemplations. All which I might defend by the Authority, and confirm by the Suffrages of the greatest Philosophers.

My

My Time, my Speech, my Breath, would fail me, even but lightly to run over the principal Heads of these Things. For no Words can justly describe the Limits, can fully contain the Advantages, can perfectly exhaust the Praises of that Science, which wanders through and encompasses the Heavens, the Earth, and the Seas. I should therefore be very unwise either to give myself much Trouble, or tire your Patience in a Matter so much spoke of by all, and by you, I imagine, sufficiently understood. Though methinks I have neither wandered from the Purpose, nor out of my Sphere, in thus exercising your Patience; since there can be no Introduction more suitable, or more profitable to the Mathematics than Patience itself; nor is any Person well qualified for these Disciplines, but he whose Ears have learned patiently to bear an insipid and empty Oration of less than two Hours long without Loathing or Weariness. I rightly named it an empty Oration, and therefore the more seasonable (for who can become eloquent or abound with Speech free from Blame with the Diet of dumb Fishes?) But if I find it to have been very disagreeable to you, I shall easily comfort, yea congratulate myself with this strong Argument and certain Augury, that I have to Day performed the Part of an accomplished Mathematician, *i. e.* a most wretched Orator. I have done.

ISAAC BARROW.

MATHEMATICAL LECTURES.

LECTURE I.

*Of the Name and general Division of the
Mathematical Sciences.*

BEING about to treat upon the *Mathematical Sciences*, according to my Office, before I enter into the inner Parts of the Edifice I chuse to tarry a little at the Entrance; and that I may humour, or rather oblige those who come less prepared to such Studies, shall first of all touch upon certain *general Things* belonging thereto (a). This, to pass by all unnecessary Circumstances, I shall closely assay to do in the following Method. First, I shall discourse a few things of the *Name* of these Sciences; then of their *Object* and the Division arising from thence; next of the manner of handling the *Object*, or investigating and demonstrating its *Properties*; (where an occasion will offer itself of enquiring into the Principles these Sciences assume, the Differences of the Propositions they exhibit, the twofold Method of demonstrating by *Analysis* and *Synthesis*, and other Matters of like kind) lastly, I shall perhaps subjoin something historical concerning their *Rise*, *Progress*, and *Increase*.

(a) Ἐξορμηθῆναι.

B

In

In the first Place, as to the *Name* ; The word *Mathematics*, (*i. e. Disciplines*) in its proper and primary Signification seems common to every acquired Science, and vulgarly means no more than to attain to the Knowledge of something we have hitherto been ignorant of ; in which Sense *Sextus Empiricus* disputing against all the Arts made publick, (*viz. Grammar, Rhetoric, Logic, &c.*) inscribes his Book against the *Mathematicians* : also the chief Authors of Antiquity use the word *Mathematics* for any kind of Learning whatsoever ; so *Plato* : (*b*) *They*, says he, *who are by nature Arithmeticians, do shew themselves ready to learn the whole Mathematics, i. e. every thing, which is capable of being learned.* In like manner (*c*) *Aristotle* ; *Every kind of Learning and mental Mathematics (or Discipline), is made from a previous Knowledge* : Among which he reckons his (*d*) *Culinary Mathematics, or Discipline of preparing Victuals.* But what are these, when many hundred such Instances occur here and there ?

Whence these Sciences are after a peculiar manner stiled *Mathematical*, *i. e. Disciplinal* ; and the (*e*) *Mathematics*, or Sciences acquired by *Discipline*. Sometimes they are called in the singular Number the *Mathematic*, as by (*f*) *Aristotle.* *It is the part of an Optician to shew the Reason of the Rainbow, either simply or according to the Mathematic*, meaning *Geometry*, from whence the *Optician* draws his Conclusions. Lastly, by a certain *Metonymy* of the Action for the Object, they are frequently called *Matheſis*, the *Discipline*. For all which Names many different Reasons are assigned by different Persons.

(*b*) Plat. 7. de Rep. (*c*) Arift. 2. Post. Anal. Initio.
 (*d*) Lib. 1. Polit. cap. 7. (*e*) Τα μαθήματα.
 (*f*) Οἷον τὸ περὶ τῆς ἰριδῆς τὸ μὲν γὰρ ὅτι φυσικῶς εἶδεναι, τὸ δὲ
 διότι Ὀπτικῆ, ἢ ἀπλῶς, ἢ κατὰ τὸ μάθημα. 1. Anal. Post. c. 13.

Some think they have this Name from their extraordinary *Evidence*, *Certitude*, and *Constancy*, because no other Knowledge destitute of these Qualities seems to deserve the Name of *Discipline*, neither ought any one to imagine himself to have learned that, which he does not perceive clearly, embrace firmly, and retain resolutely (*g*). He that gropes in Darkness, fluctuates in his Opinion, (*b*) or may be biassed in his Judgment in respect of any thing, can by no means be said to have learned that thing. And since these Conditions agree with the Sciences we are treating of, either solely or at least in a more peculiar manner than with any other, they therefore merit the Title of *Disciplines* or *Mathematics*, to be appropriated to them, by way of *Eminence*.

Others think them so denominated, because being something difficult in themselves they require the previous help of a Master or Interpreter, and ought to be applied to with very great Study and Attention: according to that Saying of *Plato* (*i*). *The Mathematics are no where set by, and are faintly applied to, by reason of their Difficulty, and because the Students require a Guide, without which they are not to be acquired.* And *Proclus*, at the End of the first Commentary upon his first Element, seems to assign a Reason of this sort; which, because by some it is more severely carped at than thoroughly understood, I shall therefore relate. According to him, the Method of attaining the Knowledge of things is threefold, *viz.* First, by *Sensation*, or the Impression coming from without. Secondly, by *Opinion*, or the inward Motion of the Fancy: And thirdly, by the discursive Operation of the Mind searching out, and as it were rousing from Sleep, the internal Images that lie

(*g*) *Arist.*(*b*) 1. *Post. Anal.* c. 2.(*i*) 7. *de Rep.*

treasured up in it. - Which last may be appositely called *Discipline*, as being a kind of (*k*) *Remembrance*, and because the word (*l*) *Discipline* may properly respect any Knowledge for the acquiring of which we come, not indeed perfectly, yet in some measure, prepared from a certain previous (though somewhat obscure Notion) of the thing to be learned; in which Case the Mind executes the Office of a Mistress teaching and instructing herself. And because this Method of acquiring Knowledge agrees principally to the Mathematics; as being such, which, to use the words of *Proclus*, *do promote Knowledge, excite Contemplation, purify the Thought, draw forth the internal Images, take away Forgetfulness and Ignorance, and dissolve the Chains of Error*; also since the Followers of *Pythagoras*, who either first invented or first cultivated the *Mathematics*, do say the same Things of them; they are therefore so named by reason of the manner of inventing them, and because they merit the Title of *Discipline*. These are nearly the words of *Proclus*, which are indeed both subtle and ingenious.

But perhaps all these Things are more elegantly devised than truly asserted. For neither does this Term (with many others) seem so much taken from nice Reasoning, as from common Use, depending on a probable Cause. Therefore I rather judge the *Mathematics* to be so called, because when the *Grecians* first begun to apply themselves to the Study of Arts, these only were delivered in the Schools; the other Arts being not yet invented for the Instruction of their Youth. They, I say, studied these Arts alone, no other being known to them, except *Philosophy*; which was not so much learned

(*g*) Ἀνάμνησις from μνησκειν, to bring to mind.
 (*h*) Μάθησις from μαθάνειν, to learn. Which words, he takes notice, may seem to proceed from the same Original, and be of near signification.

by

by the Youth, as anxiously sought after by the Aged : for in those early Times there was scarce found any among them, who attained to a Pitch of Learning, so bold as to profess himself a (i) *Philosopher* ; and those wandering Sophists that first arrogated the Title, were deservedly punished by *Socrates*. But some time after, the other *Arts of Writing, Speaking and Disputing* took their rise : And indeed the Art of *Writing* (I mean *Grammar*) is referred by most to *Aristotle* ; at least it seems to have taken its beginning about his Time ; for the mention which is made by *Plato* concerning the Invention of (k) *Grammar* by *Theuth* an *Egyptian*, I take to be only spoke of the bare Description of Letters, (indeed a most useful and wonderful Artifice) but in no wise of Grammar Precepts adjusted into the form of an Art, concerning which I am of Opinion scarce any thing was known to *Plato*. The Art of *Speaking* (or *Rhetoric*) *Cicero* relates to have been begun by the two *Sicilians*, *Corax* and *Tisias*, a little before *Plato*, and was put into writing by *Aristotle* : But these two only seem to have drawn the first Draughts, or begun the Foundations of the Art, as *Aristotle* intimates at the End of his Book of *Sophistry*. Lastly, the Art of *Disputing* (or *Logic*) took its beginning from *Eleates* *Zeno*, a Cotemporary and Companion of *Socrates*, and scarcely was reduced by *Aristotle* to the Method of an Art (as himself testifies) ; at least it was wholly unknown to the (l) *Pythagoreans*, and most other Philosophers before *Plato*. It seems in that Infancy of Learning these popular Arts were not yet grown to Maturity : It had not yet come into Men's Heads that either the Faculty of writing skilfully, or speaking eloquently, or disputing sub-

(i) Or *Master of Wisdom*.
(l) *Arist.* 1. *Metap.* cap. 6.

(k) *Plat.* in *Philebo.*

tily were to be drawn from Precepts ; which peradventure they either thought natural to every one, or believed them to be more easily attainable by daily Use than an elaborate Education ; nor did they think themselves much deceived by Experience.

In those first Ages then Men's whole Studies were employed about these two Studies, *viz.* *Mathematics* and *Philosophy* ; the former of which was wont to be instilled into the Youth by skilful Masters in the Schools, the latter did exercise the Contemplation of the more Aged in their more secret Retirements : the former prepared Men's Minds, and paved their Way to the latter. To which may be referred that triple Commentary writ by *Pythagoras*, which *Laertius* mentions, (*m*) *viz.* *Institutive*, *Civil*, and *Natural*, in which the whole Literature of those Times does seem to be comprehended : nor is it much to be doubted, but the *Institutive* did signify the same with (*n*) *Mathematical*, by which previous Discipline that Prince of Philosophers prepared the Way to both the following Parts of Philosophy, *viz.* *Civil* and *Natural*. And that threefold Gradation of the Doctrine of *Pythagoras*, which *Gellius* speaks of, seems to belong to the same ; according to which, his Followers were called first (*o*) *Hearers*, next *Learners*, and lastly *Philosophers* ; *i. e.* first they studied to hold their Tongues and exercise their Ears, as ignorant of all things ; then to learn something, or endeavour after some Science ; lastly to be wise, *i. e.* to acquire the Knowledge of the most excellent things. To this also *Plato* refers when he calls the *Mathematics* a (*p*) *previous Education*, or as it

|| (*m*) Παιδευτικόν, πολιτικόν, φυσικόν. (*n*) Μαθηματικόν.
 (*o*) Ἀκροατικοί, μαθηματικοί, φυσικοί. Lib. 1. c. 9. (*p*) Προ-
 παιδία. 7. de Rep.

were a Prelude to Philosophy. And in the first Book of *Proclus* they are named (q) *The Way to Education*: Likewise *Xenocrates* elegantly titles them (r) *The Handles of Philosophy*; and others the (s) *Steps and Ascents* by which Men mount up to the Knowledge of sublime Things. Lastly, *Theon Smyrnæus*, the ancient Expositor of *Plato's Mathematics*, according to the Notion of his Predecessors, very well represents the whole Method of searching out Wisdom by the sacred Knowledge of the Mysteries anciently in use; the Degrees or Parts of which were five in all, viz. (t) *Purgation, Initiation, Inspection, a perfect Knowledge in the Mysteries, and the Dignity of Bliss*: Where *Philosophy* (viz. rational, civil, and natural) may be fitly compared to the *Initiation*, *Theology* to the *Inspection*, and *Mathematics* to the preparatory *Purgation*; by which last the un instructed were driven far from the Mysteries, as profane and unqualified.

I suppose then enough has been said to convince us how justly these Sciences are called by the Name of *Mathematics*, (i. e. *Disciplines*) because they alone were at first learned by *Disciples* or Scholars, and not only Things but Names also do of right belong to them who are first in Possession. The Name which they first obtained from the Verity of the Thing, they afterwards deservedly retained (use confirming the Possession); and may they retain it not in vain, but be studiously learned by young Persons with that Industry which is requisite.

(q) Ἡ κατὰ παιδύσειν ὁδός. pag. 6. (r) Λαβὰς τῆς φιλο-
σοφίας. (s) Κλίμακας καὶ ἐπιβάσεις. Τῶν αἰεὶ ὄντος ἢ γεω-
μετρικῆ γνώσεως ἐστὶν ἔλκειν ἄρα πρὸς ἀληθείαν ψυχῆν εἰς αὐτὴν καὶ
ἀπυργαστικὴν φιλοσόφου διανοίαν, πρὸς τὸ αἰὼν χεῖν· ἃ νῦν κάτω, εἰ
θεῖον, ἔχομεν. Plat. 7. de Rep. (t) Καθάρσιος, τελετή,
ἰστορία, ἰεροφαντεία, ἐυδαιμονισμὸς.

But while I am considering the Name *Mathematics*, it may perchance be worth the while to take Notice of that most shameful Abuse of it, which prevailed among the *Roman* Writers of a worser Age, who commonly applied it to the basest and most worthless kind of Men, to the *Astrologers*, (or rather (u) *Casters of Nativities*) *Fortune-tellers*, *Cunning-Men*, *Soothsayers*, and other such like paltry Knaves of that pestilent Rabble. Whence *Tacitus* speaks of the *Mathematicians* as a *Brood of Fellows treacherous to those above them, false to those who put their Trust in them; which* (says he) *in our City will be always prohibited, and yet always retained.* And it is recorded that the Senate passed a Decree for banishing the (w) *Mathematicians* and *Conjurers* out of *Italy*. What an unequal Pairing is here! much like the coupling of Birds with Serpents, or Lambs with Tygers. And *Seneca* says of the genuine *Mathematicians*, or *Soothsayers*, (x) *that they sometimes speak Truth.* But many hundred such like Instances are to be found in *Suetonius*, *Tacitus*, and other degenerating Historians of that Time. Whence *Gellius* says, (y) *The Vulgar call those Mathematicians who are properly Soothsayers.* Which vile Abuse of a Word signifying the most noble and honourable kind of Literature, shews the gross Ignorance of those Times, which were degenerating into the utmost Barbarity of Language: forasmuch as a Confusion of Names does sometimes argue an Unskilfulness of Things. But in a better Age, when Learning flourished more among the *Romans*, the *Mathematicians* were

(u) Ἀστρομανίσι. (w) Annal. 1. (x) Patere
 Mathematicos aliquando Verum dicere, qui illum ex quo Prin-
 ceps factus est omnibus Annis, omnibus Mensibus efferunt. *Se-*
neca in ἀποκολοκυντάσει Claudiana, (y) *Gell. Lib. 1.*
 cap. 2.

in greater Esteem, and *Cicero* carefully distinguishes them from that Rascality of Jugglers that arrogated to themselves the Foreknowledge of future Events. (z) *Do ye imagine*, says he, *that they, who are said to divine, can resolve whether the Sun be greater than the Earth, or so great as it seems; and whether the Moon has an inherent Light, or borrows it from the Sun? &c.* These things, as he goes on, belong to *Mathematicians* and not to *Soothsayers*: A Judgment indeed worthy of *Cicero*, *Dignum sapiente bonoque*. But more than enough has been spoken concerning the Name.

Lest therefore I should seem to act the Part of a *Philologer* rather than a *Mathematician*, to come to the Purpose, let us in the next Place consider the *Object* of *Mathematics*: From the various Kinds, or different Consideration of which, the Science itself is divided into various Parts. In handling of which, we will first, according to the Examples of others, deliver what is for the most part agreeable to the common Opinions; then make a more curious Enquiry concerning the Thing itself, and explain what sort of Object the *Mathematics* respects, how far it extends itself, how it is limited or distributed into Parts, and what is our own Opinion. Also, laying aside all Authority, we will now and then produce certain (a) *Paradoxes*, i. e. Things contrary to Opinion, but not perhaps (b) contrary to Reason. For I design not to follow all Things in the beaten Road, neither to undertake any thing rashly; but will freely discuss whatsoever offers itself worth the Enquiry, and not fear strenuously to avouch every thing that seems agreeable to Truth; yet submitting all I say to be examined and decided by the Judgment of your Candour and Sagacity.

(z) *Cic. de Divin.*(a) *Παράδοξα.*(b) *Παράλογα.*
There.

Therefore, as to what pertains to the general Object of *Mathematics*, it may seem wonderful that it has no proper Name agreeing to it, either in *Greek* or *Latin*. For (c) *Aristotle* improperly makes τὸ ποσὸν to be the common Genus of both *Multitude*, as it is numerable, and *Magnitude* as it is mensurable; which Word properly signifies *Quantity*, and only respects *Number*. And, on the contrary, *Quantitas*, by which Word the *Latins* use to express the τὸ ποσὸν of *Aristotle*, denotes *Magnitude* only, and cannot properly be referred to *Number*. Which Defect of a common Name to *Magnitude* and *Multitude* is perhaps an Argument that the Antients had no common Conception of them: Whether they had any with respect to the Thing, we will hereafter take notice. But whatsoever becomes of the general Object, it is plain the *Mathematics* is conversant about two Things especially, viz. (d) *Quantity* strictly taken, and *Quantity*; or, if you please (e) *Magnitude* and (f) *Multitude*. By others they are called *Continued* and *Discontinued Quantity*, the Appositeness of which will be spoke to hereafter.

But because both *Magnitude* and *Multitude* may be considered in a double respect; viz. either as they are mentally separated, or abstracted from all Matter, material Circumstances, and Accidents; (i. e. are considered generally in themselves, without regard to these Things); or as they inhere in some particular Subject, and are found conjoined with certain other physical Qualities, Actions and Circumstances: Hence arises the Division of *Mathematics* into *Pure* or *Abstract*, and *Mixed* or *Concrete*. Which Division (g) *Plato* seems to in-

(c) V. *Metaph.* cap. 13.
and τὸ ποσὸν, strictly taken.
πλήθος.

(d) In *Greek*, τὸ πλήθος,
(e) τὸ μέγεθος. (f) τὸ

(g) In *Philebo*.

imate, when he asserts some *Disciplines* (expressly signifying *Arithmetic* and *Geometry*) to be *Pure*, *Prime*, and (*b*) *Principal*; and others *Impure*, *Secondary*, and less exact. The Parts of *Pure* or *Abstract Mathematics* do absolutely respect the general Nature and proper Affections of *Magnitude* and *Number*; but the *Mixed* or *Concrete* Parts consider the same as applied to certain Bodies and particular Subjects, conjunctly with the Force of Motion and other physical Accidents. Whence these latter are by *Aristotle* called (*i*) *Physical* and *Sensible*; and by others (*k*) *Physico-Mathematical*.

Pure Mathematics then is only twofold, viz. *Geometry*, which searches the Nature, distinguishes the Species, and investigates the Properties of *Abstract Magnitude*; and *Arithmetic*, which considers *Multitude* or *Number* with its Species and Affections after the same manner: But *Mixed Mathematics* is manifold according to the various Species or different *Quality* of the Matter, which is the Subject of *Magnitude* or *Multitude*; nor consequently is it the same Way divided, either by the antient or modern Philosophers, as we will shew by and by. In the mean time we will give a few Examples, for Illustration's sake, concerning the different Method of considering the Things we have spoke of. For example, a *Right Line*, which is a Species of *Magnitude*, may be conceived either absolutely and most universally, according to its Definition, as the most simple Dimension, designing the shortest Interval between any two Points; under which Consideration it has certain general Properties either presupposed or demonstrated by the Geometrician: or it may be considered as being drawn from the Center of the Sun to the Center of the

(b) Ἡγεμονικῶς. (i) Φυσικότητις, *Auscult. Phys. Lib. 2. cap. 2.*
 (k) Ἀσθητικῶς, *Anal. Post. Lib. 1. cap. 13.*

Earth it signifies the Distance of those Bodies : or as representing a Ray of Light it strikes upon some Body, rebounds from it, passes through such a Medium, and is turned or bent this Way and that Way : or as being fixed at one Extreme it carries about or sustains a Weight made fast to the other, and serves to determine the *Momentum* according to its Distance from the immoveable Center : or as representing a musical Scale or Rule it exhibits on its Divisions the various Proportions of Sounds. According to each of which different Ways, the *Geometrician*, *Astronomer*, *Optician*, *Mechanic* and *Musician* consider a Right Line respectively. In like manner a *Sphere* may be considered, as a Figure produced by the Rotation of such a *Plane*, bounded by such a *Superficies* ; divisible in such a wise, endued with a certain Proportion to other *Homogeneous Magnitudes* ; by which means the *Geometrician* examines its Nature and Affections : or as placed at such a Distance, and illuminated uniformly or ununiformly through such a Medium with such a Light it exhibits such a Form of itself to the Beholder ; which is the Use made of it by the *Optician*, and much the same by the *Astronomer* : or as immersed in any Matter it obtains a Power of descending towards the Center of the Earth, called Weight or Gravity, and according to the various Disposition and Situation of its Parts, its Connexion with other Matter, different Sustentation or Suspension it either entirely rests, or is inclined to certain Parts, or moved to such a Limit ; in which respect it is considered by the *Mechanic*. Lastly, the *Arithmetician* handles Numbers one Way, to discover their general Affections ; and the *Musician* another, that he may accommodate them to express the Proportions of Sounds. And these Examples may suffice.

But

(1) But the mental *Abstraction* we spake of is not the only Property of *Mathematics*, but is common to all Sciences. For every Science considers the Nature of its own Subject abstracted from all others; forms its own general Precepts and Theorems; and separates its own Properties from the Properties of others, examining the former, and dismissing the latter. (m) For example, *Physics* considers the constitutive Principles, Matter, Form, &c. of Body in general; then the Affections common to all Bodies, viz. Quantity, Place, Motion, Rest, and the like; from whence it descends to the next lower Species, investigating their particular Natures and Properties; but meddles not with particular Bodies or Individuals, as well because they are innumerable and distinguished from one another by innumerable Differences, as because being treated sort by sort they may be adapted accordingly. The same way *Geometry* proposes Magnitude for the Subject of its Enquiry, not the peculiar Magnitude of this or that Body, but Magnitude taken universally; together with its general Affections, viz. Divisibility, Congruence, Proportionality, a Capacity of different Situation and Position, Mobility, &c. declaring these to be inherent to it, and after what manner they are so: Next it defines the various Species of Magnitude, (viz. a Line, Superficies, and a Body or Solid) and particularly draws forth and demonstrates their distinct Properties; continually dividing these Species into others more contract, and searching and proving their Affections by universal Propositions, Rules and Theorems lawfully demonstrated, till it has wholly exhausted its Subject, and descended to the very lowest Species. And these Theorems howsoever more or less general as to their Matter, may be

(1) *Arist. Metaph. XI. 1.*(m) *Arist. Metaph. XI. 3.*
truly

truly and properly accommodated to Subjects particular to themselves. True *Mathematical Abstraction* then, is such as agrees with all other Sciences and Disciplines, nothing else being meant (whatsoever some do strangely say of it) than an Abstraction from particular Subjects, or a distinct Consideration of certain things more universal, others less universal being omitted and as it were neglected. But enough of this.

Our next Business should be to handle the Division of *Mathematics* in a more distinct manner; but, if I am not mistaken, the Time admonishes us to reserve that for the following Lecture.

L E C T U R E II.

Of the particular Division of the Mathematical Sciences.

THE Disquisition we begun in our first Lecture, concerning the Division of the *Mathematical Sciences*, we will now assay to pursue more distinctly, as was then proposed, delivering in the first place the Method of the Antients, and afterwards our own Method. (n) The *Pythagoreans* who, as *Aristotle* says, were the first among the *Greeks*, that meddled with *Mathematics*, divided them into *four Parts*, of which, two were *Pure* and *Primary*, namely *Arithmetic* and *Geometry*; and the other two *Mixed* and *Secondary*, as *Music* and *Spheres*, i. e. *Astronomy*. And the Reason which they gave for this Division, according to (o) *Proclus* and *Boethius*, was, because since the Species of

(n) 1. Met. 5.

(o) Procl.

the general Object are two, to wit, *Multitude* and *Magnitude*, each of which may be two Ways considered; viz. *Multitude* either simply as subsisting in itself, or respectively with reference to the Sounds whose Proportions it expresses; and *Magnitude*, as it is fixed in a (*p*) Place, or is carried about with Motion; hence arise these four Parts of *Mathematics*. Thus did the *Pythagoreans* of old divide the *Mathematics*, I suppose, because they had not yet applied themselves to the other Parts, such as *Optics*, *Mechanics*, &c. which the curious Diligence of after Ages, and Time, the Inventor of all Things, brought forth and devised.

And that of (*q*) *Plato* differs not much from this most ancient Division, who distributes the *Mathematics* into five Parts, *Arithmetic*, *Geometry*, *Stereometry*, *Music*, and *Astronomy*, to which *Theon Smyrnæus* reduces all Things in *Plato* relating to the *Mathematical Sciences*. The Division, I say, of *Plato* differs from *Pythagoras's* no more than this, because, according to him, *Geometry* being taken more strictly, only signifies the Doctrine of (*r*) *Planometry* or the Mensuration of *Planes*; whereas in the other it extends to the whole Science of *Mensuration*, and consequently also comprehends under it *Stereometry* or the Mensuration of *Solids*. But why *Plato*, a Man of so universal an Education, should confine the *Mathematics* within such narrow Limits, and add no other Disciplines to them, I think proceeds from hence; because, in his time, others were either not yet invented, or not sufficiently cultivated, or at least were not yet received into the Number of the *Mathematical Sciences*.

Nor is it a wonder to find their Number encreased by *Aristotle*, by the addition of *Optics*, *Mechanics*, and *Geodesy*; forasmuch as these Studies, a little after

(*p*) *Boeth. Initio. Arithmetices.* (*q*) 7. de Rep. (*r*) Ἐπιπέδωμετρον.

Plato, especially being recommended by so great a Man, began to grow apace, and in a short time made an immense Progress. But these adventitious Parts are sometimes reckoned by *Aristotle* among the Mathematical Sciences, and sometimes disjoined from them, because they obtained a (s) middle Place, being equally Sharers of *Physics* as well as *Mathematics*. For instance, when he says *Optics* shews the reason of the Rainbow either absolutely, or as it requires the Help of (t) *Geometry*; here he plainly separates *Optics* from *Geometry*; and again he elsewhere distinguishes the (u) sensible Sciences, such as *Optics*, from the *Mathematical* ones.

But afterwards, according to the Testimony of *Proclus*, when the *Mathematics* was farther extended, and enlarged by the more diligent Study of succeeding Times, being as it were completed by its own Numbers, *Geminus*, a famous Geometrician, who flourished about the Age of *Pompeius M.* (and others of the same Degree of Learning) distributed it after this manner. They supposed some Parts of the *Mathematics* to be conversant about (w) Things only perceptible to the Understanding; and others about (x) Things sensible: to the former belonged the principal and leading Sciences of *Arithmetic* and *Geometry*; and to the latter the six following Parts, viz. *Geodesy*, *Logistics*, *Optics*, *Canonics*, *Mechanics*, and *Astrology*. Under these Terms they included the whole of *Mathematics*, as a Body composed of so many Members, which they again subdivided into other lesser Joints or Articles. *Geometry* they distributed into *Planometry* and *Stereometry*, (and perhaps it would not have been amiss to have added *Grammometry* or the Mensuration of Lines) *Arithmetic* into the Theories of *Linear*, *Plane*

(s) 1. Anal. Post. cap. 13. (t) Τὸ μάθημα. (u) Ἄσθητικαί.
 (w) Τὰ νοητὰ. (x) Τὰ αἰσθητὰ.

and

and *solid Numbers*. *Geodesy* they distinguished from *Geometry*, because it only measures such Figures as are perceptible to the Senses by sensible Instruments : as when *Proclus* measured Heaps rising in a Point for Cones, and Wells for Cylinders, by the help of Chords, Rules, and Plumb-lines contrived for that purpose. In like manner *Logistics* they distinguished from *Arithmetic*, because it considers not abstract Numbers, but applies them to things occurring to the Senses ; as when it is sought how many Parts of its Orbit a Star passes through in a given Time ; how many Soldiers are required to compleat a Battalion ; or for what Expences a House may be erected. *Optics*, as the Offspring of *Geometry*, (borrowing from thence its Rays and visual Angles) they subdivided into three Branches ; *viz.* *Optics*, properly so called, which may not unsuitably be called *Adjective*, because it unfolds the Reasons of things adspectable (*i. e.* offered to the sight) in a direct View ; as why parallel Lines proceeding to a great Distance do seem to coincide ; and why a Square beheld afar off appears in the Figure of a Circle ; *Catoptrics*, which examines the Appearances resulting from Rays reflected by an opaque Body, or bent in their Transit through a different pellucid Medium (this they took in a more extensive Sense to comprehend that also which is now commonly called *Dioptrics*, designing another thing by the word *Dioptrics*, as we shall see anon : And *Sciography*, (now called *Perspective*, *Scenography*, *Projecture* or the Art of Projection) which delineates upon any Superficies the Traces or Footsteps made by Rays emitted upon it from any adspectable Thing, representing its Figure, Position, Distance, and other Circumstances justly and beautifully. Next they named that Discipline *Canonic*, *Harmonic* or *Musical*, which makes a Judgment of the apparent Proportions of Sounds, measuring them on the Divisions

sions of a Canon or musical Scale, with a regard also to the Assistance of the Ears. Mechanics, or the Art of discovering the weight and motive Power of any massy Body, they divided into three Kinds; viz. *Organopoëtics*, which shews the Structure and Use of Instruments, especially military: *Thaumastopoëtics*, which performs things to be wondered at by the Impulse of Winds, the Power of Weights, and Tension of Nerves or Strings imitating the Motions of Life (to which consequently are referred *Pneumatics* or the Art of making Wind-Engines, *Horrbopics* or the Art of Balancing, *Centrobarycs* or the Art of the Center of Gravity, *Automatapoëtics* or the Art of making Self-movers): And (*y*) *Spheropoëtics*, which contrives material Spheres in such sort as to exhibit all the heavenly Motions upon them. Lastly, *Astrology*, which considers the Order of the mundane System, and the Motions, Figures, Magnitudes, Distances and Influences of the celestial Bodies; this they distributed into *Gnomics*, which measures Time by the Shadow of a Gnomon or Stile; *Meteoroscopics*, which resolves the different Elevations of the Stars, their Distances from one another, &c. And *Dioptrics*, which examines the Stars apparent Magnitudes and Intervals by the help of *Diopters*, i. e. certain Instruments which convey and direct the visual Rays. But *Tactics*, i. e. the Art of rightly disposing an Army of Men, they purposely banished out of the Number of Mathematical Disciplines, though it computed their Legions and formed their Camps by the help of Logistics and Geodesy; just as the Historian (according to their way of arguing) is not to be accounted a Mathematician, because he relates the Climates of Countries and Circumferences of Cities. Such was the Division of Mathematics instituted by *Geminus* and his Contemporaries, somewhat more copious indeed than that of *Pythagoras*

(*y*) Σφαιροποιία.

and

and *Plato*, as comprehending the principal Sciences which vulgarly go by the Name of *Mathematics*, but in my Opinion far from being sufficiently just and accurate. For first of all, it is a very weak and slippery Foundation to depend upon, that the *Mathematics* are conversant about Things *intelligible* and Things *sensible*, because in reality every one of its Objects are at the same time both intelligible and sensible in a different respect; intelligible as the Mind apprehends and contemplates their universal (*z*) Ideas, and sensible as they agree with several particular Subjects occurring to the Sense: For who does not view with the Eye and feel with the Hand all the particular Dimensions of Bodies? But there is no reason why the Doctrine of Generals should be separated from the Consideration of Particulars, since the former entirely includes and primarily respects the latter. (*a*) Why *ex. gr.* should one Science treat of an intelligible Sphere, and another of a sensible one? when these, as to the Verity of the Thing, are altogether the same, and as to the Action of the Mind subordinate; nor can any thing be attributed to the intelligible Sphere (*i. e.* one understood universally) which does not perfectly agree with the sensible (*i. e.* with every particular one): Whence it is altogether amiss to disjoin *Geodesy* from *Geometry*, and *Logistics* from *Arithmetic*. But permitting the Foundation to stand, at least this Division cannot be accurate, but will be found altogether lame and imperfect; for the Multitude of sensible Things, to which Number and Magnitude may be applied, is too diffusive to be circumscribed within these Limits; and consequently, if this Supposition be admitted, the Field of Mathematics will become far too wide and extensive; as will appear more clearly anon. And so much for the Division of

(*z*) *Arist. Met. Lib. 2. c. 3.*
Lib. 1. c. 24.

(*a*) *Anal. Post.*

Geminus, which yet most Mathematicians of a later Date do embrace ; saving that some banish hence Geodesy and Logisticks ; as *Blancus* in his Book concerning the Nature of the Mathematical Sciences ; *Peter Herigon* before his *Cursus* ; and *Guldinus* in the *Prolegomena* to his *Centrobarycs* treating of the Division of the Mathematics. These constitute two pure and primary Parts, namely, Geometry and Arithmetic, and four mixed and subaltern, *viz.* Optics, Mechanics, Music and Astronomy, which they again subdivide various Ways into Parts more contracted. There occur also other Divisions of these Disciplines invented by the Moderns, some more compleat and accurate, others less ; whose Number it would indeed be difficult to enter upon, and not very profitable ; because most an end the manifold Division and Subdivision of things into their minutest Parts rather tends to breed Confusion, than to remove it (*b*) : especially since many or all of these are liable to the same Exceptions with the forementioned Division of *Geminus*. Wherefore passing them by, we will consult the thing itself, and impart what is our own Judgment.

And this is my Opinion, first, that there is really no Quantity in Nature different from what is called *Magnitude* or *continued Quantity*, and consequently that this alone ought to be accounted the Object of Mathematics ; whose most general Properties it enquires into and demonstrates in the first Place, next its less general ones, and lastly, the Affections agreeing to each. This being supposed for the present, (which will hereafter be sufficiently proved) as to what belongs to the Sciences termed *Mixed Mathematics*, I suppose they ought all to be taken as Parts of *Natural Science*, being the same in Number with the Branches of *Physics*, except those that are merely (*c*) *Effective*, as many perhaps are ;

(*b*) Proclus, pag. 21.

(*c*) Ποιητικά.

such

such as *Painting, Sculpture, Statuary, Architecture*; to which may be adjoined all their kindred Arts taken from *Physics*. For these mixed Sciences are stiled *Mathematical* for no other Reason, but because the Consideration of *Quantity* intervenes with them, and because they require Conclusions to be demonstrated in *Geometry*, applying them to their own particular Matter. And, according to the same Reason, there is no Branch of natural Science that may not arrogate the Title to itself; since there is really none, from which the Consideration of *Quantity* is wholly excluded, and consequently to which some Light or Assistance may not be fetched from *Geometry*. For *Magnitude* is the common Affection of all physical Things, it is interwoven in the Nature of *Bodies*, blended with all corporeal Accidents, and well nigh bears the principal Part in the Production of every natural Effect. All *Bodies* obtain their own Figures, and execute their own local Motions; by which means, if not all, yet the most and chiefest Effects (whatsoever admits of a philosophical Explication) are performed, for the determining and comparing of which the Theorems of *Geometry* do often conduce. But if we make our Calculation thus, and name every kind of Learning *Mathematical*, which either requires, or any way uses the Help of *Geometry*, so far *Medicine* itself will be a Part of *Mathematics*; because, as (d) *Aristotle* notes, the Physician takes the Cause from *Geometry*, why orbicular Wounds, as being more capacious than others, are more difficult to heal: and because *Hippocrates*, for the same Reason, advised his Son to study *Geometry*, that he might more perfectly understand the Situations, Luxations, Contritions and Exemptions of the Bones. Also by a like Reason *Politics* may

(d) Anal. Post. c. 13.

be ascribed to the Mathematics, because it requires the assistance of Geometry, as well for Ornament in Peace, as Safeguard in War; for the elegant building of Houses, the strong Fortifications of Cities, and the commodious Conveyance of Waters; also for the right Discharge of every military Office, the pitching of Camps, disposing an Army, inventing of Engines, and applying them to use. Whence (e) *Plato*; *There is indeed, says he, a vast Difference between a Man's being expert and inexperienced in Geometry for the setting out of Camps, the possessing of advantageous Places, the ranging a Battalion in close Order or extending it farther, and the representing all other Figures of that Kind by which an Army ought to be disposed in Battles or Marches.* Whence, at least *Tactics* and *Poliorcetics* (i. e. the Art of besieging Towns) with every kind of Architecture, ought to be numbered among the Mathematical Sciences. But to return to Physics, I say there is no Part of this which does not imply Quantity, or to which geometrical Theorems may not be applied, and consequently which is not some Way dependant on Geometry; I will not except even *Zoology* itself, (i. e. the Science of living Bodies) which of all others seems to be most foreign. For does not the certain Figure, apt Proportion, and due Position of the Members come into Consideration in examining the Structure of a living Body? Cannot the Walking, Flying and Swimming of Animals, the Method of moving forward, sustaining and poising their Bodies, be examined and proved according to the Laws of Geometry? And many such things will offer themselves to him who examines any other Part of Nature. I confess there are some Parts of Physics where Quantity occurs more frequently than in others, and consequently

(e) 7. de Rep.

where

where the Knowledge of Geometry is more needful ; such as those *ex. gr.* which treat upon the heavenly Bodies, because by reason of their too great Distance from us, we can scarce know any thing at all of them, besides their apparent Figures, their Magnitudes, their Intervals, their Progresses, and the Periods of their Motions : whence it comes to pass that the whole Science almost of the celestial Luminaries seems to be Mathematical, because all the Knowledge we can attain of them respects or depends upon Quantity. Hence have we *Astronomy* with its Parts ; *viz.* *Systematics*, which enquires into the Disposition of the principal mundane Bodies, with their Situation in respect of one another : *Spherics*, which teaches the apparent diurnal Motion common to all heavenly Bodies, with its Conjunctions and Accidents : And *Theorics*, which contemplates the Motions of the Planets and the Affections proceeding from thence. To which may be adjoined the Sciences drawn from or dependent on these ; *viz.* *Chronology*, (or at least that Part of it stiled *Technical*) which justly divides the Intervals of Time from the periodical Courses of the Sun and Moon ; and *Gnomics*, which distinguishes the Particles of their diurnal Motion, discovering in like manner their Altitudes and Declinations from the Shadows of opaque Bodies : Also hither are referred *Cometology*, and the Doctrine which treats of new Stars, sometimes appearing out of the common Course. Moreover because the spherical Figure of the Earth is discovered to be the sole Cause why the Light of the heavenly Bodies, as to Continuance of Time, Species, or Situation, is different to the Inhabitants of different Places, therefore *Geography* is also reckoned to the Mathematics ; because in it the Geometrical Conclusions concerning the Sphere are entirely necessary to be well considered and understood. And for the same Reason *Nautics* (or the

Art of *Navigation*) is annexed, which directs a Ship's Course by Angles made with the Meridian, and determines its Place in the vast Ocean with the Time of the Day, from celestial Appearances. Again, because the Animal Vision is conceived to be performed by Rays proceeding like Right Lines from any assignable Point of the (enlightning or enlightened) Object towards its correspondent Point in the Eye, and consequently what Geometry demonstrates concerning Right Lines (and the Figures they constitute) may be adapted to these Rays; hence *Optics* is referred to the Mathematics: whose Parts are, *Catoptrics*, which considers the Appearances coming from Rays reflected by an opaque Body; and *Dioptrics*, which draws the Consequences of Radiation infracted by a different Medium: To which are annexed the effective Arts respecting Vision; viz. *Perspective*, which teaches the Method of representing justly and neatly the Species or Figures of visible Objects upon any Table, especially Planes; *Graphics* or *Painting*, which adds Colour and Shade to Perspective; *Engraving*, *Carving*, *Statuary*, and the like. And if the Figure of the Air's Undulation could be the same way discovered, by which Sound is performed, and the Sense of Hearing impelled, there would doubtless arise thence a new Part of Mathematics to be celebrated by the Name of *Acoustics*, or the Science of Sounds. Also *Haptics*, *Goustics*, and *Ospbrantics* (or the Sciences of Touches, Tastes and Smells) would by a similar Reason merit to be chosen into this Order; and, if these Sensations be performed by such Motions, Philosophers might smell by guess. However, as to what pertains to the Sense of Hearing, because from the certain Division of a sonorous String, or from the Length of two Strings differing according to a certain Proportion, both stretched alike, if both be struck with a Quill, there is found a deter-

minate

minate Habitude of the Sounds produced, which wonderfully answers to the Proportion of the Strings according to the Degrees of Sharpness and Flatness, and consequently is explicable by Numbers (or at least by Right Lines), hence arises that Part of Mathematics termed *Music, Harmonics* or *Canonic*, which (as some love to speak) is subaltern to Arithmetic; but perhaps it would be more rightly subordinate to Geometry. Moreover, since the Power of descending directly towards the Earth, called Weight, which is inherent to most Bodies endowed with sensible Magnitude, from whatsoever efficient Cause it proceeds, may in fact be limited and obtain its Degrees from these things conspiring together, *viz.* partly its own Bulk, partly the Situation of its Parts, and partly the Distance from the immoveable Center of its Motion about which it is turned; and by like Reason since the Power of resisting these ponderous Bodies, of sustaining, elevating, or any how removing them from their Place is determined and depends on the same Causes; hence the Disciplines concerning the Rest or Motion of these Weights whether considered absolutely or comparatively (*i. e.* as they mutually respect one another) are ascribed to the Mathematics; because they require the help of Geometry to determine their Magnitudes, Positions and Distances: of which kind are *Statics* (*i. e.* the Science of Weights) *Mechanics, Centrobarycs, Horrbopics*, and the like. And to these may be referred *Automatopoetics*, or the Art of making Machines moveable, not by an extrinfecal Impulse, but from an internal Gravity, or elastic Virtue within themselves. Yea, because no local Motion as to its Duration, Impetus, Intention, Direction, and all kinds of Differences can be otherwise estimated in itself, or compared with another Motion, but from the Spaces (*i. e.* the Right or Circular Lines) it passes through, therefore

fore most Parts of Physics, and all their kindred Arts universally wherein local Motion principally obtains, are to be accounted Mathematical, so far as they make use of the Dimension of Lines or Spaces appropriated to Geometry: From whence accrues a plentiful Crop of Sciences to the Mathematics. For hence is the Doctrine concerning the Motion of Bodies descending naturally in what proportion they are accelerated: concerning the Motion of Projectiles which is compounded of a natural and acquired Motion, what Curve Line they describe: concerning the throwing of Darts and the Impulse of missive Weapons discharged from Engines of War, what Force they have, and how the Machines serving them are to be disposed so as to hit the Mark aimed at with the greatest Force and Certainty: also concerning the Conveyance of Waters upwards by the Force of Air or Wind, by Compression, Rarefaction, Attraction, Evacuation, or whatsoever other Cause. These particular Sciences, I say, treating of such Things, and the like, do very much encrease the Parts of Mathematics: Of which kind were *Belopoëtics*, *i. e.* the Art of making Battering-Rams; *Balistics*, or the Art of making and using Engines of War wherewithal to cast Darts or Stones; *Pneumatics*, the Art of making Machines which go by the Force of the Air or Wind; *Hydraulics*, *i. e.* the Art of making Engines to carry or raise Water, with all sorts of Water-works, &c. Hence I conceive it appears sufficiently plain (as I purposed to shew) that *Mathematics*, as it is vulgarly taken and called, is adequate and co-extended with *Physics*. Also I have at the same time shewn (as by the by, yet designedly) how far every particular Science aspires at the Dignity and Title of *Mathematics* by its own Merit, and by what means the Compass of this Science has come to that vast Extent it now is; so that

that it may be said of it, as once it was said of the *Roman Republick*, *it sinks under its own Weight*. Nay it is come to that pass, that even the Learned seem to fall into the Error of the Vulgar, and whatsoever can be any way expressed by a Diagram or shadowed to the Sense by a visible Image, that is, *ipso facto*, supposed to belong to the Mathematics. Whereas in reality those which are called *Mixed* or *Concrete* Mathematical Sciences, are rather so many Examples only of Geometry, than so many distinct Sciences separate from it: for when once they are disrobed of particular Circumstances, and their own fundamental and principal Hypotheses come to be admitted (whether sustained by a probable Reason, or assumed *gratis*) they become purely Geometrical. For example, suppose a Star or celestial Point in the Heavens (*i. e.* the indefinite Space) be carried through a right, circular, elliptic, or any other Line, with an uniform or apparently equable Motion respecting some determinate Point, in a certain Time (*i. e.* with a certain Velocity determinable by the Proportion of Numbers or Right Lines); these Things, I say, being supposed, all the consequent Discourse used in *Astronomy* becomes purely Geometrical. And how much the more simple and evidently possible the Hypotheses are taken, so much the nearer do these Arts approach to Geometry: From whence *ex. gr.* that Part of Mechanics treating of the Center of Gravity, and that Branch of Optics vulgarly called Perspective, are not unfitly numbered among the Parts of Geometry, because they scarce require any thing which is not granted and proved in that Science, nor use any other Principles or Reasonings than what are strictly Geometrical. But enough of these Things for the present.

Perhaps some may wonder, that while I am endeavouring to make a perfect Enumeration of
all

all the Parts (at least the principal Parts) of Mathematics, I am wholly silent about that which is called *Algebra* or the *Analytic Art*. I answer, this was not done unadvisedly. Because indeed *Analysis*, understood as intimating something distinct from the Rules and Propositions of *Geometry* and *Arithmetic*, seems to belong no more to *Mathematics* than to *Physics*, *Ethics*, or any other Science. For this is only a Part or Species of *Logic*, or a certain Manner of using Reason in the Solution of Questions, and the Invention or Probation of Conclusions, which is often made use of in all other Sciences. Wherefore it is not a Part or Species of, but rather an Instrument subservient to the Mathematics: No more is *Synthesis*, which is the manner of demonstrating Theorems in Contradistinction to *Analysis*. But of these we will treat more clearly hereafter, when we come purposely to discourse of the Mathematical Ways of *Invention* and *Demonstration*.

It was nearly for the same Cause, that I designedly passed by *Logistics*; for neither do I reckon this among the Parts of Mathematics, because it has no Object distinct and proper to itself, but only delivers a kind of Artifice for designing Magnitudes and Numbers by certain Notes or Symbols, and collecting and comparing their Sums and Differences, founded in *Geometry* or *Arithmetic*: From whence it constitutes no Part of Mathematics distinct from *Geometry* or *Arithmetic*, but is entirely contained in them. But I perceive a more weighty Complaint will be brought against me, because *Arithmetic* itself, hitherto accounted almost the chief of all Sciences, seems as it were banished by me out of the Confines of Mathematics; at least is wholly omitted. The Fact I cannot deny, but the Reason why I did it, having not now Opportunity, I will shew in the next Lecture.

LECTURE

L E C T U R E III.

Of the Identity of Arithmetic and Geometry.

WHEN I treated in the foregoing Lecture concerning the Division of the Mathematical Sciences, I affirmed the Whole of Mathematics to be in some sort contained and circumscribed within the Bounds of Geometry. And indeed concerning the other Sciences then mentioned, I imagine no Body will much deny, but they are conveniently enough reduced to Geometry. But now I have brought a harder Task upon myself, to shew allowable and fit Causes for expunging *Arithmetic* out of the List of Mathematical Sciences, and as it were degrading the most noble Science from the Degree which it has been so long possessed of. Albeit I am conscious to myself that I have committed no such Fault. Be it far from me to take away or seclude a Science so excellent and profitable as that of Numbers from the Mathematics. I will rather restore *it* into its lawful Place, as being removed out of its proper Seat, and ingraff and unite it again into its native Geometry, the Stock from whence it has been plucked. Nay, my Conscience would not permit me to oppose so illustrious and venerable an Authority, and obtrude such a monstrous Paradox upon you, if I did not put great Confidence in the Cause I have undertaken, and thought it very much to the Purpose of Mathematics, that Arithmetic be accounted not only like and of kin to Geometry in Nature (or, according to the Saying of (f) *Archytas* of *Tarentum*, that antient *Pythagorean* Philosopher,

(f) *Nicomachum* 1. *Arith.*

its

its Sister) but more nearly conjoined, yea altogether the same, and wholly indistinct from it. For I am convinced that Number really differs nothing from what is called Continued Quantity, but is only formed to express and declare it; and consequently that Arithmetic and Geometry are not conversant about different Matters, but do both equally demonstrate Properties common to one and the same Subject; and very many, and very great Improvements will appear to be derived from hence upon the Republic of Mathematics.

I. For first of all it appears that there is neither any general Axiom nor particular Conclusion agreeing with Geometry (which respects Magnitudes not taken absolutely, but in Comparison with one another according to certain Proportions of Equality or Inequality, *i. e.* as they are capable of being designed and compared together by Measures) but what by the same Reason also agrees with Arithmetic: And on the other hand that nothing can be affirmed, concluded, or demonstrated, concerning Numbers which may not in like manner be accommodated to Magnitudes; whence accrues a remarkable Light and vast Improvement to both Sciences; the Cause being removed of superfluously repeating and demonstrating Theorems by Nature altogether the same, also of often solving the same Problems. For the Confirmation of which, innumerable Examples as well as Arguments may be produced, and the whole Doctrine of Proportions is a most remarkable Instance.

II. This Coalition of Numbers and Magnitudes being admitted, a plentiful Accession accrues to each Discipline. For it will be a very easy thing to discover and demonstrate very many Theorems concerning Numbers by the Assistance of Geometry, which, by keeping within the common Limits of Arithmetic would scarcely, if at all, be capable
either

either of Investigation or Demonstration: Also very many Things may be more briefly and clearly found out and demonstrated from hence. And reciprocally, the Ratio's or Reasons of Numbers being well understood will communicate not a little to the more evident Explication and strong Confirmation of many Geometrical Theorems. We will illustrate the Matter with an Example or two. It is an Arithmetical Theorem, that *the Sum of an infinite (or indefinite) Series of Numbers increasing from Nothing to a certain Term, which is the greatest according to the Ratio of the square Roots of Numbers continually exceeding one another by Unity, (i. e. as 0, 1, $\sqrt{2}$, $\sqrt{3}$, &c. ad infinitum) is subfesquialter the Sum of as many equal to the said greatest Term*; Which Theorem I am of Opinion can never be exactly demonstrated by any Method in Arithmetic itself: but it is plainly deduced from Geometry. For if the Diameter of any Parabola be conceived to be divided indefinitely into many equal Parts, then the Right Lines which are ordinately applied to the Diameter, through the Points of the Divisions, will proceed in the same Ratio, as is shewn in Geometry: But the Parabola which is constituted of these, whether Right Lines or Parallelograms, is there also demonstrated to be Subfesquialter to the Parallelogram, upon the same Base and of the same Height, or which is the same thing, to the Sum composed of as many Right Lines or Parallelograms equal to the greatest: From whence, the Agreement of Arithmetic with Geometry being supposed which we desire to advance, it plainly follows, that a Series of Numbers of this sort is Subfesquialter the Sum of as many equal to the greatest.

But we will propose an easier Example, not much unlike the former. *The Sum of a Series of Numbers infinitely decreasing in a triple Ratio*
(i. e. as

as 1, $\frac{1}{3}$, $\frac{1}{9}$, $\frac{1}{27}$, &c.) till the last or least Term be nothing is to Unity as 3 to 2; or the same Sum excluding Unity is equal to $\frac{1}{2}$; This Theorem (which for easiness and Perspicuity's sake, I have proposed in a determinate, viz. a triple Ratio) although it may be demonstrated Universally (g), yet I think, by making Use of a continued Quantity, it will be shewn much more clearly and expeditiously, at least more handsomely and elegantly (FIG. I.) *Ex. gr.* Suppose the moveable Point A to be carried through the Right Line A Z, with an uniform Motion: Also imagine the Point E to be moved uniformly through the same, but with a Velocity subtriple the Velocity wherewith the Point A is carried; then, in whatsoever time the Point A runs through the Right Line A E in the same time will the Point E run through a third Part of A E, suppose E F. Also in whatsoever time the former Point runs through the Right Line E F, in the same time will the latter run through the third Part of E F, suppose F G, and so on, *ad infinitum*, till the Point A overtake E in $\mathcal{A}E$. Now if we suppose the Line A E to be Unity, then will E F be $\frac{1}{3}$; F G $\frac{1}{9}$, and G H $\frac{1}{27}$, &c. *ad infinitum*, according to the Hypothesis; but it appears that the Line A E run through by A is triple the Line E $\mathcal{A}E$ which is run through by E in the same time, because A is supposed to move with three times the Velocity of E. Therefore E $\mathcal{A}E$ is to A E (*i. e.* the decreasing Series including Unity is to Unity) as 3 to 2. Q. E. D. This Theorem universally is as follows. *The Sum of any Series of Numbers continually de-*

(g) Thus;

$$Z - 0 . Z - a : : a . \mathcal{C} .$$

$$Z \mathcal{C} = Z a - a a .$$

$$a a = Z a - Z \mathcal{C} .$$

$$\therefore \frac{a a}{a - \mathcal{C}} = Z .$$

creasing

creasing from Unity infinitely, or to Nothing, in any Proportion, will be to Unity, as the Antecedent, or greater Term of the Proportion, is to the Excess of the Antecedent above the Consequent. Or the same Sum, excluding Unity, will be to Unity, as the Consequent, or lesser Term of the Proportion, is to the Excess of the Antecedent above the Consequent. For the foregoing Premises being supposed, let the Ratio be given between R and S, and let A E represent Unity, as above; then because A Æ (*i. e.* A E + E Æ) : E Æ :: R : S. therefore (by dividing the Proportion) A E : E Æ :: R - S : S, *i. e.* Unity is to the Sum of the proposed Series, as the Excess of the Terms of the Proportion is to the lesser Term : And again, because A E . E Æ :: R - S : S. therefore A Æ . A E :: R : R - S, by Conversion, *i. e.* the proposed Sum including Unity is to Unity, as the greater Term of the Proportion is to its Excess above the lesser. So easily are Arithmetical Conclusions, (otherwise sufficiently intricate and difficult to be investigated) drawn from the Consideration of Geometry. Thus doth the one Science require the help of the other, and after a friendly sort conspire together.

(b) III. Moreover another Convenience arises from this Conjunction, because (contrary to what one not long ago of a great but mistaken Genius ventured to assert, that he might veil his Mistakes in Geometry, and decline the easy Confutation of his Errors) no Geometrical Argument is of Force, which agrees not exactly with an Arithmetical Calculus, and consequently all false Reasonings committed in Geometry may be examined and refuted most easily,

(b) Quoniam Arithmetica instrumentum est omnis supputationis, & numeri sunt termini, quibus quælibet magnitudo significatur, non dubium est, quin per numeros fieri possit omnis magnitudinis calculus. *Maurolycus* in Prolegom. ad Lib. II. Arithmet.

D

certainly,

certainly, and justly, by Arithmetical Computation : Also all true Conclusions, and lawful Demonstrations in Geometry may be confirmed and illustrated by Help of an Arithmetical Calculus : Which Consideration being presupposed and established, the Method of treating Geometry will be found nowhere to differ from the Calculations of Arithmetic.

These Conveniences, not to mention more at this time, will flow to the Mathematics by taking away the Difference between Geometry and Arithmetic, or by constituting and asserting their Identity. But that they are the same, the very Name of Geometry (which signifies measuring the Earth) does confirm, at least it creates a strong Suspicion : And much more so, that more general Name *Metrices* (*i. e.* The Science of *Measure*) which *Plato* prefers before the Name *Geometry*. For what, I beseech you, is meant by *Measure*, but the Notification or Expression of Magnitude by Number ? *Measure*, (*i*) says *Aristotle*, is that whereby *Quantity* is known ; but *Quantity* is known as *Quantity*, either by *Unity*, or by *Number*. If then *Geometry* include *Number* in its Name, why ought it not to comprehend it in the Thing ? Moreover, because τὸ πᾶσιν includes a peculiar Respect unto *Number* (by which one Word the general Object of Mathematics is wont to be designed) this may discover that because the Conceptions of *Magnitude* and *Number* could scarce be separated in the Name, they can therefore hardly be so in the Mind. But this will appear plainer by weighing and examining the Nature of *Number* a little more circumspcctly. Wherefore

1. I remark that no *Number* of itself signifies any thing distinctly, or agrees to any determinate Subject, or certainly denominates any thing. For every

(b) X. *Metaph.* cap. 1.

Number

Number may with equal Right denominate any Quantity : and in like manner any Number may be attributed to every Quantity. For instance, Any Line A may be indifferently called *One, Two, Three, Four,* or any other Number, (or if you please, *Simple, Double, Triple, Quadruple,* or howsoever it may be termed *Multiple*) as it remains undivided, may be cut into, or compounded of, two, three, four, or any other Number of Parts. In like manner any Number *ex. gr. 5.* may be attributed to all the Quantities A, B, C, and an Infinity of others, as they are conceived to consist of 5 Parts. Whence it appears that no Number can design any thing certain and absolute, but may be applied to any Quantity at Pleasure.

2. I observe, that as no particular Number taken separately and absolutely can signify any thing certain, so no two or more Numbers compared together can indicate any Habitude or Proportion determinate of itself. For example, the Number 3 compared with the Number 2 does neither of itself denote a Sefquialter, nor any other Proportion. For let the Line A be of 3 *Palms*, from whence it is denominated *Three*, and suppose the Line B to be of 2 *Feet*, from whence it is named *Two*; it is evident that the former Number 3 is not in a sesquialter Proportion to the latter Number 2 (for 3 *Palms* is not to 2 *Feet*, as 3 to 2) much less is any other Proportion here expressed by these Numbers, albeit otherwise they may be in a sesquialter Proportion; it being apparent that this Number 2 by which a Line is denominated *two Palms*, can never be equal to that Number 2 whereby a Line is said to be *two Feet*.

3. I note that Numbers of themselves can neither be added to nor subtracted from one another, so as in the one Case to compose a Sum, or in the other to leave a Difference or Excess. As in the

preceding Example, the Number 3 expressing *three Palms* cannot be added to the Number 2 representing *two Feet* so as to make a Sum of 5 Palms or Feet, or 5 of any other Measure notified according to the signification of these Numbers. Nor if the latter Number 2 be subducted from the former Number 3 will there arise any explicit Difference, or knowable Excess. And in like manner if 3 Angles be adjoined to 4 Right Lines, the Sum will be Nothing: Or if the Number 3 of Horses be subtracted from the Number 5 of Angels will result any Difference. How then (you will say) comes the Determination of Numbers to certain Uses? Are they not used to denote a definite Ratio and be added to and subtracted from one another? I answer, that these things do only now and then agree with Numbers, according to the Condition of the things to which they are attributed. If the things which the Numbers are brought to denote be homogeneous, of the same Name, and when compared have a mutual Proportion to one another, and consequently the one can be increased by the Addition or diminished by the Subtraction of the other; then they impart the same Attributes, Proportions, and Increments or Decrements to the Numbers by which they are denominated. As *ex. gr.* because a Line of two Feet obtains a like *Nature* and *Denomination* with a Line of three Feet, therefore the Number 2 by which the one is signified denotes a certain sesquialter Proportion to the Number 3 by which the other is denominated; the same indeed which the Lines themselves have that they denominate: and consequently the former Number 2 added to the other Number 3 makes the Number 5 (*i. e.* five Feet) for the Sum, and that subtracted from this leaves Unity for the Excess or Difference: And by almost the same Method, whatsoever Attributes among Arithmeticians are proved to agree with
 Numbers,

Numbers, they agree not with Numbers taken abstractly and of themselves, but concretely according to the Condition of the Things they are attributed to. But a certain most learned Man, and famous Mathematician of our own Nation, asserts Geometry to be subordinate to Arithmetic, applying the Universal Propositions of Arithmetic to its self; and so making Arithmetic to be of a deeper and more abstract Nature than Geometry: for which he chiefly gives this Reason. (i) *Since, says he, a Line of two Feet added to a Line of two Feet makes a Line of four Feet, it does not follow that two and two make four, but rather the former follows from the latter.* To this I answer by asking the following Question; Whence comes it to pass that a Line of two Feet added to a Line of two Palms cannot make a Line of four Feet, four Palms, or four of any Denomination, if it be abstractedly, *i. e.* universally and absolutely true that $2+2$ makes 4? You will say, that these Numbers are not applied to the same Matter or Measure; and so say I too; from whence I infer that $2+2$ makes 4, not from the abstract Reason of the Numbers, but from the Condition of the Matter to which they are applied, *i. e.* because any Magnitude called by the Name of *Two* added to a Magnitude which is denominated by *Two* of the same Kind will make a Magnitude whose Denomination shall be *Four*: Nor indeed can any thing be imagined more absurd than to affirm that the Proportions of Magnitudes to one another depend upon the Habitude of the Numbers whereby they may be expressed.

Though otherwise it is not so much owing to any Arithmetic that $2+2$ make 4, when these Numbers are applied to homogeneous Measures, as to the commonly received Signification of the

(i) D. Wallis Arith. p. 69.

Words themselves, whereby 4 either in Name or Character signifies the same with twice 2. And indeed the whole Artifice of Vulgar Arithmetic is the same Way deduced or demonstrated; for who can prove that $3+5$ equals 8, or $8-3$ leaves 5 otherwise than from the arbitrary Signification of these Words? But

4. That these Things may appear plainer I take Notice that the Condition of the Things to which Numbers are attributed are very different. For Numbers are one way attributed to Things signifying a certain Measure (*i. e.* some determinate Magnitude to which other Things of the same Kind may be referred) and another to Things agreeing together no otherwise than by a certain generical Ratio, *Ex. gr.* When I say *Three Yards*, here the several Units whereof the *Three* is composed are mutually equal and similar to the several other Units constituting every Number whereby any Length of Yards is denominated. Whence such Numbers do always keep the same Proportion to one another with the Magnitudes they denominate, and consequently do appositely serve to express those Magnitudes. But when I say *Three Mountains*, *Three Angels*, *Three Lines*, or *Three Numbers*, it is plain the several Units whereof the *Three* is composed have no necessary Equality to one another, but only a certain general Agreement or Similitude in the common Notion of a *Mountain*, an *Angel*, a *Line*, or a *Number*. *Ex. gr.* When I call 5, 7, 9, three Numbers, here the several Numbers, as they are Three, have the Ratio or Notion of Unity, and it is evident they are unequal, but yet all agree in the Notion of Number. Also if any other *Three* of Numbers be supposed, *viz.* 10, 15, 20, the former *Three* will not be equal to this *Three*. From which Consideration there arises a twofold Kind of Number: The former may be called *Mathematical,*

tical, because it is chiefly in use among Mathematicians to express, and compare together the Dimensions of Magnitudes, and because to it the Properties of Magnitudes agree, and Mathematical Conclusions are applied: The latter *Transcendental* or *Metaphysical*, because it is indifferently attributed to all Things, even to Things heterogeneous, imaginary and privative; (for we say 2 *Points*, 3 *Dimensions*, 4 *Chimeras*, 5 *Predicables*, 10 *Blindnesses*) and because some Notion of this Sort of Numbers may be found not only previous to Geometry but to Arithmetic itself: As when we define a Triangle to be included within Three Sides, also a Plane Number to consist of two, and a Solid of three Numbers multiplied together. Whence appears a Solution of the Argument, whereby *Nicomachus* endeavours to make Arithmetic by Nature prior to Geometry; because Geometry is wont to use Numbers, and require the Definitions, Comparisons, and mutual Proportions of Figures to be in the first Place explained; as when a *Triangle*, *Square*, *Pyramid*, *Cube*, and other Figures are defined from the Number of their *Sides* or *Angles*; and when the Square of a *Diameter* is demonstrated to be double the Square of its Side, a *Cylinder* triple the *Cone* of the same Height standing upon an equal Base, &c. For it will hence be easy to answer, that Geometry as well as Arithmetic borrows those transcendental Numbers it uses in framing its Definitions and delivering its Argumentations either from *Vulgar Use*, which has the Right of affixing Names to Numbers as well as other Things, or else from *Metaphysics*, which considers and defines the most general Notions of Things: Whence we see that very many Things relating to Numbers are treated of in Metaphysics. Though on the other Hand it must be confessed that perfect Geometry compleated in all its Parts stands in need of

Arithmetic, yet not as a Science in itself entirely different and foreign, but (which we shall see anon) as a Part of it: just as *Empedometry* (or the Doctrine of Planes) a Part of Geometry by Nature prior and more simple, is to be previous to *Streo-metry*, or the Doctrine of Solids, which is a Part more complex.

Nor is it hence less easy to answer the foresaid learned Man arguing thus. (*k*) *That Assertion* (says he) *concerning the Equality of the Number Five with the Numbers Two and Three taken together, is a general Assertion, which is applicable to all other Things as well as those of Geometry; for also two Angels and three Angels are five Angels.* I answer briefly: First, as before, I say it proceeds not from the abstract Notion of the Numbers that 2 *Angels* + 3 *Angels* make 5 *Angels*, but because the Numbers *Two* and *Three* are here attributed to Beings of the same *Kind* and *Name*: Moreover these Numbers, as they are attributed to *Angels*, are *transcendental*, intimating no Equality of the *Angels* to one another properly so called, but only a *Similitude of Nature*; and therefore they belong not to a Mathematical Consideration. But *Plato* perfectly understood, and expressly delivered this Distinction of Numbers that I have taken Notice of: Whose Words are worth the recital. (*l*) *Ought we not* (says he) *to attribute one Kind of Arithmetic to the Vulgar, and another to Philosophers, since their Difference is not a little? For the Vulgar do number unequal Units of those Things which are expressed by Numbers, as two Castles, two Oxen, two of any Thing, as well the least, as the greatest of all Things. But Philosophers never reach so far, unless a Man suppose one particular Unit to consist of Parts equal to another particular Unit.* Thus *Plato* refers Num-

(*k*) Pag. 73. Arith.

(*l*) Pag. 399. Fic.

bers consisting of unequal Units to the *Vulgar*, and others to *Philosophers*, i. e. *Mathematicians*: And this perhaps he had from the more antient *Pythagoreans*, as *Aristotle* seems to intimate, when he says in a *Mathematical Number* no one Unit differs from another. But to come still nearer the Matter and reach the principal Point of the Controversy.

5. I observe and assert that a *Mathematical Number* (such as we have been just now describing, and concerning which we have been chiefly speaking, though what we shall hereafter say, may also in Part be applied to a transcendental Number by a just Analogy, as far as a *Similitude of Nature* is a kind of Equality) I say that a *Mathematical Number* has no Existence proper to itself, and really distinct from the Magnitude it denominates, but is only a kind of *Note* or *Sign* of Magnitude considered after a certain Manner; viz. as we conceive it either as altogether incomplex, or as compounded of certain homogeneous equal Parts, every one of which is taken simply, and denominates an Unit; or lastly as intimating the Ratio it has to other Magnitudes, in like manner composed by a certain Method. For in order to expound and declare our Conception of a Magnitude, we design it by the *Name* or *Character* of a certain Number, which consequently is nothing else but the *Note* or *Symbol* of such Magnitude so taken. This is the general Nature, Import, and Notion of a *Mathematical Number*: But more particularly, every Number (which they call *Explicable* or *Rational*) is known and distinguished from another, consequent to the Actions of the Mind composing (or supposing to be composed) different Magnitudes from some one Magnitude which it conceives to be incomplex, by the successive Repetition of it, or the Addition of its equal. Which Repetition at first

first performed in the Mind, and then expressed in Words is called *Numeration*.

(*m*) *Aristotle* speaks very much to the Purpose. *There is, says he, a Necessity of computing Number by Addition, as of Two by the Addition of one Unit to another, of Three by the Addition of One to Two, and of Four, after the same manner.* As when I repeat the Magnitude A once in my Mind, or conceive another equal to it, that Magnitude, which is conceived to be so compounded, I design by the Name or Character of *Two*; but if I still repeat the same Magnitude A, or superadd it to the before conceived Magnitude designed by the Note *Two*, then the Conception of another compound Magnitude is formed, which I in like manner signify by the Name or Character of *Three*. And so for the rest. But we will illustrate by an Example what we have said above concerning the general Notion of Number. Suppose *ex. gr.* any Line A; it is plain that no Number peculiarly agrees to this, on the Part of the Thing: But if we imagine it composed of some Line by the triple Repetition of itself, as is already explained; or which comes to the same Thing, that it is divisible into three Parts (for it is all one to be composed and to be resolvable into three equal Things) we will therefore call it *Three* or *three Thirds* of A, and denote it with a suitable Character. But if we conceive the same A to be an Aggregate of (or divisible into) seven equal Lines, of which same equal Parts another Line B makes (or is resolvable into) Ten, hence the Line A will be called *Seven* or *seven Tenth* Parts ($\frac{7}{10}$) of the Line B. And if the same Line A be supposed no way compounded or divided, it will obtain the Name and Character of *Unity*. Again, if the aforesaid A be apprehended as

(*m*) *Met.* 13. cap. 9.

a Mean

a Mean Proportional between any Line B consisting of (or divided into) two equal Lines, and one of those Lines, *i. e.* between the whole of B and its half, or between any Right Line and its Double; then the Line A will be designed by the Name or Character of the Square Root $C^{\frac{1}{2}}$ of the Number $\frac{1}{2}$, or 2 respectively; as the Square Root of $\frac{1}{2}$ B ($\sqrt{\frac{1}{2}} B$) or the Root of 2 C ($\sqrt{2} C$.)

6. Whence consequently it follows that there are three Differences or Species of Numbers, (besides *Unity* which is as it were the Fountain and Original of Numbers) *i. e.* *Integers*, *Fractions*, and *Radicals* or *Surds*. Of which *Integers* are the *Names* or *Symbols* of Magnitudes, shewing their Composition from certain equal Parts, every single one of which is named *Unity*, as if the Magnitude A consist of six equal Parts or of one Part six times repeated, A will be termed six. But *Fractions* (among which I reckon *Mixed Numbers* consisting of an *Integer* and a *Fraction*) are the *Notes* of any Magnitude intimating its Composition of equal Parts, not indeed absolutely but by comparing it with some other Magnitude composed of Parts equal and of the same Name with the Parts of the former: Or *Fractions* are the *Symbols* of any Magnitude equally composed by a certain Method, exhibiting its Proportion to another Magnitude, which is composed of the same equal Parts. As if A be composed of six equal Parts, and B of nine of the same, then will A be six ninth Parts of B ($\frac{6}{9} B$), or A will be to B as six to nine; *i. e.* the same Magnitude, which is here stiled *Unity*, if taken six Times composes A, if nine times, B. Lastly, *Radical* or *Surd Numbers* are *Notes* shewing a Magnitude to be any way in a *Mean Proportion* between some assumed homogeneous Magnitude equally composed according to the *Exigence* of the Number applied, whether

whether *Integer* or *Fractioned*, and its Part supplying the Place of Unity ; or which is the same, between any Magnitude taken simply and undivided and consequently holding the Places of Unity, and another so multiplied as the adjoined Number requires : *ex. gr.* the *Square* or *Second Root* of the Number 3 denotes a *Mean Proportional* between any assumed Magnitude, and its Triple. And the *Cubic* or *Third Root* of Three designs the first of two *Mean Proportionals* between any assumed Magnitude, and its Triple. Also the *Biquadratic* or fourth Root of the Number 5 signifies the first of three *Mean Proportionals* between any Magnitude and its *Quintuple* ; and so in like manner for others.

Now as to what pertains to these *Surd Numbers* (which, as it were by way of Reproach and Calumny, having no Merit of their own are also stiled *Irrational*, *Irregular*, and *Inexplicable*) they are by many denied to be Numbers properly speaking, and are wont to be banished from Arithmetic to another Science, (which yet is no Science) *viz.* *Algebra*. And by this means they demutilate Arithmetic of its noblest and most profitable Member ; for while we are measuring Magnitudes and comparing them together, we oftner in our Computations light upon these *Surds* than upon *Rationals*, which they call Numbers. But with me it is beyond all Doubt, that these have the same Right to be accounted Numbers, and equally belong to the Science of Numbers, with any other *Integer* or *Fraction*, since they are equally apt and necessary, for expressing, comparing and determining Magnitudes, (wherein as we have already hinted the whole Ratio, Import, and Use of Number consists) and since there is no general Property or Operation consonant to *Integers* or *Fractions*, which does not also equally agree with these. *Ex. gr.* I as readily conceive

ceive what is meant by the *Square Root* of 3 Yards as what is denoted by three Yards itself or $\frac{1}{3}$ of a Yard, and can as truly represent it from the Force of its Signification. For if a Right Line A be assumed equal to a Yard, and another B equal to three Yards, and a *Mean Proportional* be found between these, as is shewn in Geometry, then the Right Line found will be that which is designed by the *Square Root* of 3 Yards. And these Numbers by the Direction of most certain Rules may be mutually added to and subtracted from one another, drawn into and applied to, or divided by, one another, and any way computed, measured, or brought to express the Proportions of Magnitudes.

Wherefore there is no Reason, why they ought not to be taken for Numbers or be excluded from Arithmetic. But these Numbers, since they cannot even in thought itself be abstracted from all Magnitude, do make it sufficiently evident that Number differs nothing in reality from Magnitude: and therefore *Stevinus* does not incongruously term them *Geometrical*. For what does $\sqrt{2}$ signify abstractly? Does it signify the Root of the abstract Number 2? But this Number in that Respect has no Root, *i. e.* there is no Number, Integer, or Fracted, which being drawn into itself produces 2. Nor is it a Mean Proportional between 1 and 2, for there is no such Mean Number to be found. We must therefore have recourse to Magnitude, to conceive what is designed by this Number. For though there be no Mean Proportional to be found between the Number 1 and the Number 2, yet there is a Mean Magnitude between the Magnitude signified by the Name *One*, and that denominated by *Two*, which may fitly be designed by the Name of *the Square Root of Two*. And the same of Fractions, which do well nigh constitute the principal Part of Arithmetic, as intimately denoting

noting and implying *Composition* and *Division*, the proper Affections of Magnitude which agree with all Things else only fecondarily, and for the fake of Magnitude adjoined. He *ex. gr.* who fays or conceives $\frac{1}{2}$, fays or conceives nothing at all but that fome Magnitude is compofed of two Parts, of which another Magnitude makes three ; or that fome Magnitude is divided into three equal Parts, two of which he conceives or fays to be affumed. Nor do Integers otherwife exprefs and represent Magnitudes, becaufe thefe alfo include *Composition* or *Division* in their Notion.

Whence by the by we may know how to judge concerning the Opinion of that great Man we have fometime mentioned, who to fhew that Arithmetic is much more extenfive than Geometry, entirely transfers the whole of *Algebra* from Geometry to Arithmetic, determining Algebraical Equations to afcend higher than Geometrical ones, and denying that Geometry affords as many *Dimensions* as Arithmetic exhibits *Degrees*; with more to the fame Purpose. All which Things notwithstanding may be very eafily difcuffed, by faying that by thefe Algebraical Equations or Dimensions, or Arithmetical *Degrees*, either nothing at all is underftood and really fignified, but all are imaginary Chimeras and mere Monfters ; or elfe they have fomething answering to them in Geometry, which they do fignify and represent. As in Reality there is no Number, no Algebraical Power, no Arithmetical Degree, to which innumerable Magnitudes may not answer, in every Kind ; fuch Magnitudes being appofitely represented and expreffed by thefe Numbers. For inftance, let the *Biquadrate* or *fourth Power* of the Number *Three* be fupposed. To represent this Power Geometrically affume any Magnitude, it's all one whether it be Line, Superficies, or Solid, but it will be more fimple if you take a Right Line,
fuppofe

suppose A. Let B be the *Triple* of this, and let the Ratio of A to B be so continued, that 5 Right Lines A, B, C, D, E, are continued Proportionals; and E will be a Right Line to be denoted by the fourth Power of *Three*. For if A be called 1; B must be 3; C, 9; D, 27; and E, 81; or the Biquadrate of *Three*. We have therefore a Geometrical Biquadrate of the Number 3, or the Line B, which that Number designs. And by a like Reason any Arithmetical Degree or Algebraical Power may be exhibited Geometrically. Therefore Arguments of this Sort contain nothing of Strength. I could produce many more Things to this Purpose, but I am weary of dwelling out of the Way any longer, upon a Thing so apparent.

Notwithstanding (*n*) *Aristotle* pronounces Arithmetic to be more accurate than Geometry. For *Things*, says he, *consisting of fewer Principles are more accurate, than those understood by Addition, as Arithmetic is more accurate than Geometry.* And elsewhere more expressly. (*o*) *That Science is more accurate which consists of fewer Principles, than what is only to be understood by Addition, as Arithmetic is more accurate than Geometry. I say by Addition, as Unity is a Being understood without Position, but a Point is to be understood only by Position: Which is thus explained by Proclus; Arithmetic is indeed more accurate than Geometry, for its Principles respect Simplicity. Unity implies no Position, a Point does, and a Point requiring Position is the Principle of Geometry, Unity of Arithmetic.* These Things are neither all agreeable to the Truth nor depend upon a good Foundation. For what Science can be more accurate than Geometry? What Science can afford Principles more evident, more certain, yea I will add, more simple, than Geo-

(*n*) I. *Metaph.* cap. 2.

(*o*) I. *Anal. Post.* c. 24.
metrical

metrical Axioms, or exercises a more strictly accurate Logic in drawing its Conclusions? But *Aristotle* and *Proclus* affirm that *Unity* (they had more rightly said Numbers) the Principle of Arithmetic, is more simple than a *Point* which is the Principle of Geometry, or rather of Magnitude. Because a *Point* implies Position, but *Unity* does not. *A Point*, says *Aristotle*, and *Unity* are not to be divided, as *Quantity*: *Unity* requires no *Position*, a *Point* does. But this Comparison of a *Point* in Geometry with *Unity* in Arithmetic is of all the most unsufferable, and derives the worst Consequences upon Mathematical Learning. For *Unity* answers really to some Part of every Magnitude, but not to a *Point*: Thus if a Line be divided into six equal Parts, as the whole Line answers to the Number six, so every sixth Part answers to *Unity*, but not to a *Point* which is no Part of this Right Line. A *Point* is rightly termed Indivisible, not *Unity*. (For how *ex. gr.* can $\frac{1}{6} + \frac{1}{6}$ equal *Unity*, if *Unity* be indivisible, and incompounded, and represent a *Point*) but rather only *Unity* is properly divisible, and Numbers arise from the Division of *Unity*. A Geometrical *Point* is much better compared to a *Cypher* or *Arithmetical Nothing*, which is really the Bound of every Number, coming between it and the Numbers next following, but not as a Part. A *Cypher* being added to or taken from a Number does neither encrease nor diminish it; from it is taken the Beginning of Computation, while itself is not computed; and it bears a manifest Relation to the principal Properties of a Geometrical *Point*. Nor is that altogether unexceptionable, which is said of *Position*; for a *Point* taken univervally is not less indeterminate, and void of *Position*, than *Unity* taken the same Way: But *Unity* taken particularly implies a definite *Position*, and all other particular Circumstances, as well as

a particular *Point*. Lastly, the Accuracy of Arithmetic and Geometry is so far from being different that it is altogether the same, drawn from the same Principles, and employed about the same Things. I might here annex many Observations and Consequences drawn from hence ; but

Not to be too tedious and prolix, I judge it will appear plain enough to every one who duly weighs what I have suggested, that, in reality, *Number* (at least that treated of by Mathematicians) differs nothing from *continued Magnitude* itself, nor seems to have any other Properties (Composition, Division, Proportion, and the like) than either from, or in respect to it, as it represents, or supplies its Place ; nor consequently that it is any Species of Quantity distinct from Magnitude, or the Object of any Science but Geometry (which is conversant about Magnitude in general) : In sum, that Number includes in it every Consideration pertaining to Geometry. Therefore the *Element Writer* (whatsoever *Ramus* can object, who taunts him with that Name) did not unadvisedly, in inserting Arithmetical Speculations among the Elements of Geometry, nay rather he did great Service to the Mathematics, and merited highly in not permitting these Sciences to be separated from one another, as if they were separate in Nature, but assigning to Arithmetic a suitable Place in Geometry. (*p*)

(*p*) Qualem certè videtur antiquitus obtinuisse ; siquidem vel ipse magnus Orator de Geometria obiter tractans, de recepto opinor Usu potius quam ex Ingenio suo dicat, *Geometriam in Numeros atque Formas esse divisam.* Quintil. T. 10.

L E C T U R E I V .

Of the Unfitness of the common Division of Mathematics into Speculative and Practical, and of the Excellence of Mathematical Demonstration.

I Have now propos'd what I thought to be of Use concerning the Division of the Mathematical Sciences; but have purposely omitted their Distribution into *Speculative* and *Practical*, as less just and necessary; since this does not so much intimate Sciences as different Respects of the same Science. For, in my Opinion, every Science is both *Speculative* and *Practical*: *Speculative*, as it *speculates*, *i. e.* seeks, investigates and demonstrates Truths (or true Propositions) agreeable to its Object: and *Practical*, as those Truths when found and demonstrated, may be referred to Use, and reduced into Practice. *Ex. gr.* The *Politician* speculates and infers, from well weigh'd Reasons, what Form of Government, and what Laws will best conduce for the public Welfare: The *Moralist* considers and pronounces (*i. e.* invents and prescribes some certain Theorem or universal Rule) what is the Duty of a good Man in such and such Circumstances: The *Physician* examines and determines, from Reason or Experience, the Nature, Virtues, and Temperaments of what they call *Simples*, whether they be in Faculty Cool or Hot, Dry or Moist, Healthful or Noxious: And so far these Sciences are *Speculative*. But if any one do use these Conclusions for the directing of his Practice, and attemperate his Actions accordingly: If he manage Affairs of State according to the Pre-script of this *Political Theorem*; if he live accord-

ing

ing to that *Moral Precept*; if he take or refuse such a Plant for the sake of his Health; then do these Sciences and Conclusions become Practical. And the same happens in our Case. The Geometrician demonstrates universally *That every Triangle is equal to one half a Parallelogram upon the same Base and of equal Height: That a Cone is equal to one third Part of a Cylinder upon the same Base and of equal Height.* Which Propositions and Rules being universally true, the Geometrician finds and approves by Speculation, and they may be always used for determining the Measure of any Triangular Area, or for comparing any Conical Vessel with its circumscribed Cylinder. Both these *Theorems* therefore may be called *Practical* as they relate to Use and Practice, but they would for that Reason be very unfitly divided into *Speculative* and *Practical*. Geometry is one simple Science which may be considered in two Respects, *viz.* it is stiled *Speculative* as it is true, and *Practical* as it is useful. The Absurdity then of this Division is clear. Notwithstanding I shall not very much oppose him who urges that such Geometrical Rules are more useful, which shew the Dimensions of particular Magnitudes, or are accommodated to some certain material Subject; though that perhaps may prejudice the main Science, and it would be better to find them no where, but affixed to their proper Fundamentals in Geometry, along with their Demonstrations, *i. e.* in their proper Place and native Order: But it ought not therefore to be thought that a Collection of Rules of this Sort do constitute a Part or Species of Geometry distinct from *Speculative*. Consequently *Trigonometry*, or the Doctrine concerning the Dimension of Rectangular and Spherical Triangles; *Altimetry*, which shews the Way of finding Distances; *Planimetry*, which teaches to describe and

measure plain Surfaces; and *Stereometry*, which compares the Measures of solid Bodies: these are not Parts of *Speculative* more than *Practical* Geometry, but belong to the same Science, which in a different Respect may be called, either *Speculative* or *Practical*.

Hitherto we have treated concerning the general Object of the Mathematical Sciences and their Division. It remains in the next Place to consider the *Mode* or *Manner* whereby they are conversant about their Object; which is certainly the same with what obtains in all other Sciences properly so called: Forasmuch as it is the Design of all Sciences to investigate the particular *Properties*, *Affections* and *Passions* of their Object together with its Essence, either as they flow immediately or mediately from it; and to shew that they do necessarily agree with it by a certain and evident *Discursus*. Though as (q) *Aristotle* takes notice, in more Places than one, this is in fact performed by some more (r) *closely* and *validly*, and by others more *loosely* and *faintly*, according to the Condition of the Matter. And this kind of *Discursus* is wont to be called (s) *Demonstration*. But it is neither my Office nor Intention to handle this Matter at large, since it properly belongs to *Logic*. He therefore that would have a more intimate Knowledge of it, and desires to taste of the Original Fountains themselves, let him consult *Aristotle* its famous Inventor and Author in his Books of *Analysis*, the posterior Books especially, where he explains the Nature of *Demonstration*, and prefixes Laws to it. But it may suffice for my Purpose

(q) V. *Metaph.* cap. 2.

(r) XI. *Metaph.* cap. 7.

(s) Ἀποδείξις, so called perhaps, because the Conclusion drawn by it appears as plainly to the Understanding, as a Thing shewn by the Pointing of the Finger appears to the Sense. For δεικνύειν signifies as much as to shew by the Pointing of the Finger, (δεικτυλοδείκτειν) Whence δεικτυλῶ, as it were δεικτυλῶ.

only

only to take Notice of his Sayings and Prescripts as they accord with the Mathematical Way of Reasoning. But if we weigh the Matter more nicely, we shall find that Demonstration agrees properly and peculiarly with these Sciences only, and cannot with equal Justice be supposed to agree with other Disciplines. Whence *Aristotle* in the Beginning of his *Ethics* excuses himself why he could not strictly demonstrate *moral Truths*; because the Rigour of Demonstration is only to be found in the Mathematical Sciences, and not in that Kind of Learning; alledging it to be equally out of the Way (*t*) to require *persuasive Arguments from a Mathematician, as Demonstrations from an Orator*. And for the same Reason he denies that a *Mathematical Exactness* should be required from a natural Philosopher: Which when that excellent Logician *Jac. Zabarella* had considered, as he somewhere testifies of himself, he diligently pursued *Euclid's Elements* over and over, that he might the better understand and explain the Nature of Demonstration. But it will perhaps be worth the Trouble, briefly to enquire into the Causes from whence this Difference proceeds; why Demonstration which is every where found in the Mathematics, should occur so seldom, or rather never in other Disciplines. And I know no other Way by which the Nature of Mathematical Demonstration will appear more easily and clearly, than by such a Comparison. And that

I. Because we do clearly conceive, and readily obtain distinct Ideas of the Things which these Sciences contemplate; they being Things the most simple and common, such as lie exposed to Senses, capable to be represented by the most familiar Examples, and therefore most easy to be understood, as containing in them nothing abstruse, intricate or unusual. What *ex. gr.* is a *Right Line*? What,

(*t*) I. *Metaph.* cap. ult.

a plain Superficies, a Triangle, a Square, a Circle, a Pyramid, a Cube, a Sphere? These are Things which we perceive clearly and distinctly, where very few Things are required, and which may be expressed in the fewest Terms, and represented by the clearest Examples. Whence it comes to pass that concerning Things so evidently and accurately perceptible it is no hard Matter to demonstrate some Truths, *viz.* such as agree with these Ideas, or are immediately inferred from them. But in other Sciences it generally falls out otherwise, because the Things which they consider are of a Nature more recondite and abstracted from the Senses, more intricate and complex, and more dark and confused to the Apprehension. *Ex. gr.* It is hard to imagine distinctly, and define exactly what is Colour in *Physics*, Happiness in *Ethics*, or the Law of Nations in *Politics*, because we have seldom any clear Notion of these Things; and if we have, it is so complex, that perhaps no two Persons have entirely the same, or we are not able to make it out to those with whom we converse. Whence it falls out, that there are almost as many different Conceptions and Explications of such Things, as there are Authors and Interpreters.

II. A second Reason is, because Mathematicians do use such Words as make their Definitions perspicuous, and without the least Ambiguity: or to speak more fully, they express their Conceptions with more adequate Terms, such as are of a certain and invariable Signification; so that, as soon as ever the Term for the Thing proposed is heard, the Conception answering to it immediately occurs to the Mind. Nor does there arise any Doubt or Controversy, about whatsoever is affirmed or denied of such Things, but every Thing apparently tends to the Certitude of the Propositions.

Propositions. But in other Disciplines, as the Obscurity, Perplexity, and Confusion of the Notions, so also the Ambiguity and Inconstancy of the Words by which those Notions are signified, do necessarily produce much Darknes and Uncertainty in their Conclusions. For in general, they neglect the Definition of their Terms, oftentimes admit Speeches improper and metaphorical, and accept the same Word in different Senses ; at least different Authors do variously take and differently describe one and the same Thing, every one accommodating his Conclusions to his own Signification or Description : From whence there necessarily arises not only an Uncertainty, but also a Contrariety of their Propositions ; the Contemplation of the Truth degenerating into Disputation, and that Disputation ending in mere Logomachy ; the principal Part of the Controversy being spent in the indefinite Signification of the Terms. And the Definitions and Descriptions, which they bring, do not only for the most Part leave these Faults unremedied, but do very often involve the Question in Obscurities and Trifles. For what Light can be had from such Definitions as these ? *Motion is the Action of a Being in Power, as it is in Power. Light is the Action of a Thing perspicuous, as it is perspicuous. The Soul is mere Action or Perfection, or it is Number moving itself.* Which Explications do rather serve to perplex and confound, than enlighten or instruct us. So that that jesting Definition of a Man, which was used by *Democritus*, is better and more useful than these : *A Man is what all of us know.* In short, if the Matter of the Propositions to be demonstrated which are Words, (*i. e.* the Symbols of the Things conceived in the Mind) have no certain Signification, it will be impossible to come at any Certainty concerning the Truth of the Propositions.

III. A third Reason why Demonstration is so peculiar to Mathematicians is, because they admit no Principles or Axioms which are not universally true, which are not proved by a continued Induction, not granted by common Suffrage, and lastly which are not supported by their own Strength, and conspicuous from their own Light ; so that what Conclusions are drawn from hence do necessarily compel the Assent of the Hearer. For who does not easily understand such Propositions as these as soon as he hears them ; and readily acknowledge them as Things most true, most plain, and agreeable to constant Experience ? *viz. That Things equal to the same Third are equal to one another : That if equal Magnitudes be added to or taken from equal Magnitudes, the Sums or Remainders will be equal : That the Whole is greater than its Part, &c.* which are Truths that suffer no Exception, and require no Proof or further Explication. But in other Disciplines, the Principles on which the Superstructure is to be raised, either for the most part may be weakened, as to their Universality, by contrary Instances, and consequently require some Exceptions, Limitations, or Distinctions, to avoid the Imputation of Falsity ; or else they are only admitted precariously, and do not force the Assent of the Hearer ; or lastly, they require farther Confirmation, or a more prolix Explication ; whence it happens, that no Conclusion, which is universally true, evident, indubitable and irrefragable can be inferred from them, nor can any stable irresistible Demonstration be erected upon Foundations so wavering and inconstant. For what Certainty, pray, can be deduced from such Principles as these ? *Nature does nothing in vain : All Things aim at good : Nothing gives what it has not : and the like.* How many contradictory Propositions by using a little Subtilty, both may
and

and are wont to be inferred from these by such as delight in Querks? For extricating and reconciling which to one another, they are forced to invent such a vast Number of little Distinctions, as is indeed wonderful; from whence results much Disputation, but no Demonstration.

IV. Like to the last is a fourth Reason, *viz.* That Mathematicians admit no *Postulates*, nor suppose any *Hypotheses* but such as are evidently possible, and most easy to the Imagination: such as according to *Proclus*, are *Easy, Helpful, Simple* and *Ready*: Such as none can refuse to grant howsoever prejudiced, unlearned, and untractable. *Ex. gr.* When 'tis supposed or required that a *Right Line* may be either drawn, or conceived to be drawn through any two Parts assignable: That assuming any Point as a Center, the Circumference of a Circle may either pass or be understood to pass through any other given Point: That any Body may be cut with a Plane: That a Semicircle may be turned about its Axis. Who will deny that these Things may be done or conceived to be done; or object against any one for supposing Things so evidently possible: Things which he sees and experiences to be done daily? But in other Sciences the Matter is far otherwise. These seem not any Way to explain the Causes of Things, nor do their Professors stick at coining *Hypotheses* suitable to their Arguments, and requiring *Postulata* which are altogether arbitrary, hard to be digested, and monstrously immodest: Things which are not only difficult to be believed, but oftentimes hard to be conceived. As *ex. gr.* When in Physics, it is required to be granted for the Explication of Vision, *That I don't know what kind of intentional Species are dispersed around from every Appearance of the visible Object.* Or according to others, *That certain corporeal Effluvia, or thin Skins, peeled from*
 6 the

the Thing objected, more fine than Thought itself, are every where carried in a direct Course towards whatsoever is placed in View: Or lastly, which is the Opinion of some, That certain Motions, Actions, or Endeavours are directed and derived with the utmost Ease and Speed from every Point of the illuminating or illuminated Object to every Point of the circumscribed Medium. No Body surely is so simple or credulous, as immediately to agree or force himself to acquiesce with any of these Hypotheses (though ingeniously devised) not only as true, but as at all possible, or in any Degree probable; because so many Difficulties occur to prevent or destroy his Faith, who does but a little attend to them. And who would not make him ashamed of his Unreasonableness that has the Forehead obstinately to require many such Things granted him? At least, who can imagine that a solid Demonstration can stand upon so loose and sandy a Foundation?

V. Moreover fifthly Mathematicians being a Sort of Men, in the highest Degree modest, and patient of Labour, do not only go upon Principles (*u*) manifestly true, and assume such Hypotheses as are apparently possible, but do beyond Measure affect a strict Paucity in both. They had rather take any Pains to demonstrate their Assertions, than beg the Assent *gratis*, or make too free with the Hearers Liberality. They desire that the Evidence and Validity of their Conclusions may be owing to the Force of their proper Reasons, and not to another's Easiness. They esteem it worth all their Diligence and Pains to grow exorbitantly rich out of a small Stock, to encrease to an immense Height of Knowledge from a little Root, and to build a vast, and no

(*u*) Arist. I. Post. cap. 25.

less firm, Structure upon a narrow Foundation. They therefore use a great deal of Labour and tedious Prolixity in deducing some Propositions, otherwise most easy, because they hate a Multiplicity of Postulates and Axioms. Upon which Account that great (*v*) Censurer (or rather Carper) *Ramus* sharply reproves *Euclid*, because he undertook to demonstrate many Propositions, which in his Opinion were sufficiently evident from their own Light, and therefore should have been passed by undemonstrated, and been reckoned among the Number of Axioms. But he might as well have gone through the whole Troop of ancient Geometricians, who were all guilty of the same Fault; and among them accuse the *divine Archimedes* himself, because he refused the Liberty of assuming more Axioms or Postulates than were necessary; and, arrogating such a Licence to himself, rather chose to propose and demonstrate his admirable Theorems with something more of Intricacy and Prolixity, which might have been done otherwise, with more Shortnets and Perspicuity. But in my Thoughts their Method seems by no means Blame-worthy, but ought rather to be very much commended and embraced. For no Diligence or Solitude should be thought too much, which is spent in establishing the first Principles of Sciences. It is far better that many Demonstrations be redundant, than for one to seem defective. Every Handle for cavilling or refusing the Assent to the Principle of any Argument as uncertain or less notorious is to be taken away from *Epicurean* Dispositions. All Suspicion, all Dread, all Hesitation is to be removed from these Disciplines, as much as may be. Nor is the Faith of Learners to be put to too much Trial, nor

(*v*) Schol. Mathem. Lib. 3.

their Minds too far strained and blunted with the Multitude of Hypotheses, nor too much accustomed to a rash Presumption. Howsoever it may not be either unprofitable or unpleasant to shew the Coherence and Affinity of the first Propositions one with another by a Syllogistical Operation: And as it is more great and glorious to subdue an Enemy with a small Force, so to erect innumerable Truths upon a few Principles procures more Admiration, and merits a greater Praise to conquering Reason. Wherefore neither do I think that curious, but ingenious, Sedulity of the great *Apollonius* at all to be blamed, much less with some to be accused of Ambition or Madness, who attempted to demonstrate that famous Axiom *of the Equality of Things equal to the same third*. Nor do I carp at the needless Study of *Regiomontanus*, who, as it is said, undertook to deduce the first Rules of vulgar Arithmetic from *Euclid's* Elements. In Imitation of whom, one of our own Philosophers, well known to all, attempted the Demonstration of that most remarkable Principle, *That the Whole is greater than its Part*.

But however what I purposed to shew appears from what has been said, it is plain, that where so much Labour is taken, and such Care used to prevent any Proposition from aspiring at the Dignity of an Axiom, and the Number of Hypotheses from encreasing to a Multitude; there it can be no Wonder, if every Conclusion be most validly demonstrated. But in other Kinds of Learning, the Reason and Method of Proceeding is different. In those do grow an infinite Crop of Axioms, which, if transcribed, would make well replenished Store-houses of Volumes. Every probable Proposition aspires at the Degree of an Axiom; and however it be assumed *gratis*, it works
all

all that is requisite for the Proof of a Conclusion. And for the Dispatch of every Question, or the Explication of a Phænomenon, a new and distinct Hypothesis is invented. From whence it happens that in what is called and accounted the same Science are found Hypotheses without Number; even as many as there are Subjects to be handled, which not only overcome the Faith of the Hearers, but confound the Memory itself; so that they can scarce by any Means be made consistent, nay do often oppose and contradict one another. And every one sees what a System of Demonstrations must proceed from hence.

VI. But again sixthly, the *Generations* of Magnitudes, by which Mathematicians do sometimes define them, and deduce their Properties are most easily perceived by the Imagination as highly possible and to the utmost Degree reasonable. *Ex. gr.* When a Circle is described from the carrying about of a Right Line one of whose Extremes is fixed; a *Cone* is formed from the Rotation of a Rectangular Triangle about one of its immovable Legs; a *Sphere* is generated from the turning of a Semi-circle about its Diameter, as an Axis: In like manner, when a *Right Line* is made from the shortest direct Motion of a Point; a *Parallelogram* from the transverse Passage of a Right Line keeping a perpetual Parallelism through the same Plane; a *Prism* or *Cylinder* from the like parallel Transit of a Rectilineal Plane Figure or a Circle; when a *Spiral* and *Quadratrix* (two *Curve Lines*) are described from a twofold uniform Motion, the one right or parallel, the other circular; a *Parabola* from a twofold Motion, the one uniform, and the other uniformly accelerated. Now no Body, who will but attend a little can deny, or in the least doubt, but such Motions may be performed; and that such Effects must necessarily result

result from them. Our Understandings cannot but clearly perceive what will follow from supposing such Generations. Therefore the Properties of Magnitudes may be easily drawn and demonstrated from such Causes.

But the Production of natural or other Things are not so manifest; neither can the Properties of the Effects proceeding from any such supposed Causes be thus deduced. *Ex. gr.* Supposing such a Complexion or Temperament of elementary Things, or so great a scorching of Sulphur, or that the Rotation of some subtle Matter prevails over its direct Passage; who dare boldly and peremptorily assert that such an Appearance will necessarily be produced to the Sight as is wont to constitute or accompany a *Red Colour*? Consequently none can demonstrate the Passions and Affections of Things from such feigned Generations.

VII. Hither also we may refer, seventhly, the accurate *Order* in which Mathematicians handle their Subjects, investigate their Truths and dispose their Propositions. (*w*) *Aristotle* takes Notice that the *Order* used amongst Mathematicians is *helpful to the Memory*; and consequently to the reasoning Faculty. In the *Order* of the Mathematics, it may be especially observed, that those first self-evident Propositions which are requisite for the Demonstration of others, *viz.* *Definitions*, *Axioms*, and *Postulates*, are wont to be carefully ranged in the Front, the Nature of our Way of Arguing so requiring: Next to these are placed the more simple Propositions which are immediately deduced from the former; then follow those that are drawn from these latter, and thus an indissoluble Chain of Arguments is carried on in an uninterrupted Series,

(*w*) *Tract. de Memoria & Reminisc. cap. 2.*

the latter still receiving Light and Strength from the former. Whence it also happens, that the Original of every Proposition may be derived even from its first Principles, its Dependance upon and Connection with them perceived, and consequently its Verity discovered by a certain and infallible Ratiocination. Again we may observe with the Mathematicians, that if any Propositions found and demonstrated be of more remarkable Note or universal Nature, if they excel either in Point of Elegance or Usefulness, these being approved and established by the Examination of skilful Persons are reserved as a Treasure, and laid up in a kind of publick Storehouse, from whence they may be drawn forth, as Use shall require, to serve for the Investigation and Demonstration of others. Of which Kind are most of the Propositions of the ancient Geometricians, which do exhibit the particular Properties of certain Magnitudes more remarkably obvious to the Mind; as the *Elements* of *Euclid*, the *Spherics* of *Theodosius*, the *Conics* of *Apollonius*, *Archimedes* of the *Sphere* and *Cylinder*, with others. These are as so many Seminaries or Storehouses of Geometrical Truths upon various Subjects, from whence innumerable Conclusions are easily deduced; or as so many Principles leading to the Invention and Probation of almost all other Propositions; or lastly, as so many *Criteria* or Touchstones by which other Truths are to be tried and examined.

In other Disciplines it for the most part falls out otherwise. For if you seek for Principles you will no where find them, or at least you will find them mingled and confounded with their Conclusions without Distinction; and like the Ships of *Aeneas* dispersed through the wide Ocean; which must needs very much disturb and impede
the

the Progress of the Student : For, as (x) *Proclus* says, *The mingling of Principles binders all Knowledge, and compares together Things that have no Relation to one another.* Nor will you observe in them any Order, or almost any Connection of the Propositions themselves ; so that you cannot trace the Origin of any particular Proposition whatsoever to its first Principles, nor can it certainly appear to you whether it is true or false ; but according to the Saying of *Hierocles*, *the Misplacing of Things deceives and perverts the Judgment.* By Reason of which, no Principles are at Liberty to be known by all or confirmed by the common Suffrage, to which every Discursus is to be referred, from which the Invention of Theorems and Resolution of Questions is to be fetched, and lastly by which the Truth of Propositions is to be examined.

VIII. Eighthly and lastly ; It may be observed of Mathematicians that they only meddle with such Things as are certain, passing by those that are doubtful and unknown. They profess not to know all Things, neither do they affect to speak of all Things. What they know to be true, and can make good by invincible Arguments, that they publish and insert among their Theorems. Of other Things they are silent and pass no Judgment at all, chusing rather to acknowledge their Ignorance, than affirm any Thing rashly. They affirm nothing among their Arguments or Assertions which is not most manifestly known and examined with the utmost Rigour, rejecting all probable Conjectures and little Witticisms. They submit nothing to Authority, indulge no Affection, detest the Subterfuges of Words, and declare their Sentiments, as in a Court of Judicature, *without Passion, without Apology* ; knowing that their Rea-

(w) Lib. 2. pag. 22.

sons,

sons, as (*) *Seneca* testifies of them, are not brought to persuade, but to compel. And by this means they preserve their Sciences pure and free from the least Stain either of Error or Doubt. In others, which are called Sciences, Things doubtful are promiscuously mingled with Things certain, Things taken upon Presumption with Things found by Experiment, Things obscure with such as are manifest, and true Things with false. Their Professors propose all Things to themselves to be examined, explained, and decided, according to what they know and what they do not know: And when they cannot bring certain Reasons, they produce any Kind of Conjecture, disguised under beautiful Colours, oftner divining than demonstrating. In fine, they plead with all their Eloquence, as for their Properties; and what they can't prove, they endeavour to persuade.

But I am afraid you will begin to grow weary with the Length and Prolivity of this Comparison. From whence notwithstanding it may in some Sort appear what Method of *Demonstration* is used by Mathematicians; which is such, that they only take those Things into Consideration, of which they have clear and distinct Ideas, designing them by proper, adequate and invariable Names, and premising only a few Axioms which are most noted and certain to investigate their Affections and draw Conclusions from them, and agreeably laying down a very few Hypotheses, such as are in the highest Degree consonant to Reason and not to be denied by any one in his right Mind. In like manner they assign Generations or Causes easy to be understood and readily admitted by all; they preserve a most accurate Order, every Proposition immediately following from what is supposed and

(*) *Sen. I. Qu. Nat.*

F

proved

proved before, and reject all Things howsoever specious and probable which cannot be inferred and deduced after the same manner.

And this Kind of Argumentation is properly *Demonstrative*, and produces the most certain Knowledge which the Mind of Man is capable of: Such as none can either deny or doubt. For if the Premises be such as no Body can contradict or make the least Scruple of, and if the Method of drawing the Conclusion be also lawful, suited according to the infallible Rules of *Logic*; what can hinder the Inferences from being necessarily true, the *Discursus* from being justly called *Demonstration*, and its *Effects*, (*i. e.* the habitual Knowledge remaining in the Mind) to merit the Name of *Science*? But yet some both have been, and still are so subtle as to deny that the Mathematics are truly Sciences, and that they afford true *Demonstrations*: whose Reasons we will consider in the following Lecture.

L E C T U R E V.

Containing Answers to the Objections which are usually brought against Mathematical Demonstration.

HAVING gone thorough what I had to say concerning the *Object* and *Division* of the Mathematics, I began in my last Lecture to speak of the Mode or Manner whereby they are conversant about their Object. To illustrate which in some measure I thought it would not be amiss to undertake a Comparison of these with other Disciplines. And hence I have not obscurely insinuated from
 2 what

what Fountains the Efficacy of a Mathematical Discursus flows, asserting its Validity *by way of Confirmation*. It now remains on the other Hand to treat *by way of Confutation, i. e.* to bear against the Assaults, oppose the Cavils, and remove the Trifles of such as impugn the Certitude and Excellence of the Mathematical Way of Reasoning.

(y) *Aristotle* styles the Mathematics the most *Accurate Sciences*. He ascribes to them an *Exact Method* as their peculiar, and every where intimates and supposes the like; so that I do not doubt but he had a View chiefly to these, when he formed the Doctrine of Demonstration which he first delivered: at least he drew most of his Examples hence, for its Illustration and Confirmation. Nevertheless there formerly have been such, and that not long ago, (and what is most to be wondred at, among the *Peripatetics* themselves who subscribe to the *Aristotelian* Philosophy, and would be thought to have drawn their Opinions from *Aristotle* himself, however opposite he be to their Sentiments) who have not stuck to deny the Mathematics to be truly Sciences, or that they afford true Demonstrations. Among the Antients indeed, besides the *Pyrrhonians* and the *Ephectici* (who equally exploded all Science, and hardly would be brought to affirm, nay feared not flatly to deny that there could be any *Certainty* in any Thing) besides these, I say, the *Epicureans*, a Sect especially spiteful against the Mathematicians, endeavoured to overthrow their Principles, and weaken their Demonstrations: *Posidonius* is said to have writ a whole Volume in Confutation of one (z) *Zeno* a *Sidonian* of this Sect. And some of the Moderns tread in the same Footsteps.

(y) *II. de Cælo cap. 7. Metap. I. cap. ult.* (z) *Proclus, p. 55.*

Though I think it not worth the while to spend much Subtilty in refuting the Cavils of those who sport with other Men's Arguments and put no Confidence in their own (who are truly Heretics, or Persons self-condemned) yet however I will examine one or two of their principal Reasons. *First* then they urge that there can be no Demonstration, but what proceeds from Principles universally true; which kind of Principles, as *Aristotle* himself testifies, can be known no otherwise than by an Induction of Particulars. But the universal Truth of Propositions cannot be gathered by Induction, both because all the Particulars cannot be reckoned over (as being infinite or indefinite in Number) and because Induction depends upon a Sense, which in most Cases is deceitful and liable to Error. Therefore there is no firm Foundation at all for Demonstration. To this principal Argument (which yet strikes not against the Certitude of the Mathematics only, but of all Science in general) I answer by asking this serious Question of the Objectors, and pressing it home to their Consciences; whether they cannot clearly perceive, and are not most fully persuaded, *that if equal Quantities be subtracted from equal Quantities, the Remainders will be equal.* If they say, they can't firmly assent to the Truth of this Proposition, but are doubtful, and afraid of being deceived by trusting to it, they must seem to all, and even to themselves, whether they will or no, as Fools or Madmen. But if they cannot refuse or avoid giving their Assent to this Truth, then they must needs have a certain Knowledge of it; for what else signifies a Certainty of Knowledge, but that the Thing known seems evidently true to the Mind of the Knower, so that all dread of the contrary is entirely excluded? It may be, you will enquire by what Means this Certitude comes, or
how

how it is gotten. I answer, by whatsoever Way the certain Knowledge of Axioms is acquired, whether by Induction and manifold Experience, or it arises from the natural Notions of the Mind, or whatsoever other Way it is attained; it is sufficient that we are intimately conscious of it, and find it impressed upon the Mind in an indelible Character: For we are not disputing about the manner of acquiring Knowledge, or the Origin of Certitude; but about the Thing itself, whether or no it be had. Perhaps I am ignorant of the Manner of perceiving by my Senses, but do I not therefore see what is before mine Eyes? Do not I hear what strikes my Ears, nor touch what is in my Hands? So certain am I of the Truth of this Proposition; certain, I say, by the irrefragable Testimony of my own Breast: and in like manner you are also certain, whatever you may pretend to the contrary: (*a*) *It does not follow (says Aristotle) that what a Man says, he also thinks*: But how, or by what Means this *Certainty* comes is not equally known, nor does it matter much whether it be known or no. The certain Knowledge of the Thing may however be some Discovery, while we are enquiring and contending about the Manner of attaining that *Certainty*.

Nevertheless in some Sort to gratify these Objectors Importunity, let us consider a little the Manner of arriving at this *Certainty*. About which in the first Place, I will affirm nothing of *Connate Notions*, a Question that would require a larger Dissertation, and carry me farther from my Design, than I am willing to go: I only take Notice that if it be true which many Philosophers of no small Note do earnestly contend for,

(*a*) Arist. adv. Heraclit. in Met.

(viz. the *Platonists* and *Stoicks*) that such natural Thoughts, original Notions, or, as (b) *Maximus Tyrius* calls them, *Seeds of Truth* are implanted in our Minds by Nature; against whose Light we cannot shut our Eyes, nor resist their Force: I say, if this be supposed, then the Thing is done, and the Method whereby we arrive at *Certainty* will easily appear, since all the *Certainty* we have is by the infallible Guide and Instinct of Nature alone: The Author of our Being gives us the Principles of Knowledge all at once, as soon as we exist; so that we yield our Assent to these *Primary Notions* no otherwise than as a Stone drops to the Ground, as the Sun darts forth its Light, and the Fire feeds upon its Fuel. But passing by this Method of attaining *Certainty*, let us proceed to others, if any there be.

The *Sense* then, when right and perfect, as it is naturally in most Men of a sound Constitution, discerns many Objects *certainly*. *Ex. gr.* such as these, *The Sun now shines; This Man is standing by*: to doubt which would rather seem the Part of an impertinent Trifler than a sage Philosopher; of one playing both with himself and others, or of one who both wrongs his own Conscience and opposes the Authority of all besides (for every one gives a most firm Assent, and full Acquiescence of Mind to the Perceptions of *Sense*); nay I may say of one unjust and ungrateful to Nature, derogating either from its Goodness or Power; as if it either would not, or could not make us capable of certainly comprehending the Truth, but had rather keep us involved in perpetual Darkness, Uncertainty and Error. *Aristotle* on the contrary will have it to be the Property of *Sense*, *That it is*

(b) Differt. 28.

always

always true, and is inherent to all living Creatures (c). Nevertheless I cannot wholly deny, but *Sense* is sometimes deceitful and the Cause of false Judgment (indeed sometimes necessarily and inevitably), when it is either ill disposed and contrary to Nature, or when the Objects are not suitably represented. But for a Person seriously to grant, that the *Sense* never certainly attains its End, that it never exhibits to the Mind the Species of the Things objected, so as to take away all Possibility of judging falsely by relying upon its Testimony; What is this, but as was just now said, to be gravely mad, to offer Violence to ourselves, and disparage our Nature? He argues much better in (d) Cicero, who says, *The Judgments of the Senses are so clear and certain, that were it in our Choice, and God demanded of us whether we were content with Senses perfect and uncorrupt, or we required something better, I can't see what we can seek farther.* — *The greatest Truth is in the Senses, when they are sound and perfect, and all Obstacles and Impediments removed out of the Way.* To which Sentiment every one agrees in Thoughts, whatsoever he may profess in Words.

But you will say, How shall I know, how shall I distinguish whether all Things be rightly suited for *Sensation* or no? I answer, there is no need for you to know or distinguish these (e) Things, since you will be necessarily convinced by the Evidence of the Thing itself, and forced to yield your Assent whether you will or no, by the Impulse of Nature. But you will return, I am oftentimes deceived by my Senses; (f) as when I sensibly

(c) Lib. 3. de Anima. cap. 3. (d) In Lucullo.
 (e) 'Αὐτὸ γὰρ ἐστὶν ἐπιστῆναι πρὸς τὸν ἕξω λόγον· ἀλλὰ πρὸς τὸν ἴσω λόγον οὐκ αἰεὶ. I. Post. cap. 10. (f) 'Ἡ γλῶττα τέττε φιλοσοφικῆ κατ' Ἐυριπίδην, ἢ φράσι' ὑδαμῶς ἐδ' ἢ ψυχῆ.

perceive that the Colours of the Rainbow are real, that an Oar is bent in the Water, that the Sun is a little Thing nigh at hand, and that a Square Figure placed at a Distance is round. Be it so, notwithstanding absolutely speaking you have a right Perception of such Things, *viz.* that the Rainbow appears, that an Oar is in the Water, that the Sun shines upon you, and that a Thing appears round; but it does not belong to *Sense*, but to *Reason*, to discern the relative Determinations of Magnitude, Distance and Figure: Your Error therefore in these Things, whatsoever it be, ought to be imputed to this, and not to that. I might explain these Things better, and more fully, but I am unwilling to immerse myself deeper, and wander farther from my Purpose in a Question altogether Philosophical. Let it suffice that it may be taken as a fixed and established Truth, a Truth granted and sincerely embraced on all Hands, that some Things, though not all, are perceived and judged of rightly by *Sense*.

But what if I assert, that the *Mind* of Man, if rightly disposed (and not out of Tune, as in Ideots and Mad People), is by its native Faculty able to discern *universal* Propositions, in the same manner, as the *Sense* does *particular* ones? *i. e.* as the Truth of these Propositions, *Socrates exists, An Eagle flies, Bucephalus runs*, is immediately perceived and judged of by the *Sense*; so these, *Contradictory Propositions cannot be both true, What begins to exist has its Rise from another; Action argues that a Thing exists*, (or as it is vulgarly expressed, *A Thing that is not, acts not*) and such like Propositions, which the *Mind* directly contemplates, and finds to be true by its native Force, without any previous Notion or applied Reasoning: Which Method of attaining Truth is by a peculiar Name stiled *Intellection*, and the Faculty of attaining it

↓

the

the *Intellect*. And what hinders but the Principles of Mathematical Demonstration may be perceived by such a Faculty? But you will say, *Aristotle* teaches, that the Truth of all *universal* Propositions, even of *first Principles* themselves are no otherwise had than from Induction. For thus he, (g) *It is manifest that first Principles are known to us by Induction; for the Sense operates thus universally.* And again more expressly in his (b) *Ethics to Nicomachus, There are some Principles from whence a Ratiocination proceeds, of which there is no Ratiocination; these are therefore had by Induction.* To which agree those Expressions taken from the same Author, *That nothing is in the Intellect which was not first in the Sense. The Intellect is as a smooth or unwritten Table.* To which may be referred such Sayings as these found in him, (i) *Nothing can be known without Imagination. He that has no Sensation can neither learn nor know any Thing.* From which it appears that according to *Aristotle*, the Principles of all Science depend wholly upon the Testimony of the Senses and particular Experiments: Which, if granted to be true, then scarce any human Reason can be supposed to come up to strict Certainty, or even arise above a probable Conjecture. But where any Proposition is found agreeable to constant Experience, especially where it seems not to be conversant about the Accidents of Things, but pertains to their principal Properties and intimate Constitution, it will at least be most safe and prudent to yield a ready Assent to it. For as we are justly accused of a rash Temerity, by suffering ourselves to be so much as once deceived by our Faith, so are we guilty of the greater Imprudence, if we shew the least Distrust, and

(g) II. Anal. Post. cap. ult. (b) Lib. VI. cap. 3.
 (i) Lib. de Mem. c. 1, Lib. III. de Anima, c. 8.

do not yield our stedfast Assent and obstinately adhere, when we still find our Expectations most accurately answered, after a thousand Researches; and especially when we have the constant Agreement of Nature to confirm our Assent, and the immutable Wisdom of the first Cause forming all Things according to simple Ideas, and directing them to certain Ends: Which Consideration alone is almost sufficient to make us look upon any Proposition confirmed with frequent Experiments, as universally true, and not suspect that Nature is inconstant, and the great Author of the Universe unlike himself. Nay sometimes, from the Constancy of Nature, we may prudently infer an universal Proposition even by one Experiment alone, as (*k*) *Aristotle* observes and confirms by a most apposite Instance. *For might we (says he) discern some Things with our Eyes, all Doubt would be taken away; not that to perceive a Thing with the Eyes is to know it, but because the Conformity of the whole Kind arises from the Sense of Seeing. Thus could we discern the very small Pores of Glass, and the Light passing through them, it would be manifest to us why Glass is transparent, because seeing the like in different Glass, we would immediately conclude the same of all.* Whence, to apply these Things to our Purpose, he that withholds his Assent from the Principles of Mathematics, even in this Respect, cannot avoid the Imputation of extream Folly and Madness: And surely there is no farther need of any Thing to demonstrate the Efficacy of a Mathematical Discursus, than the Conviction of all but Fools and Madmen.

But setting aside all Authority, after a due Examination, we have no Reason to own, that the Principles of Mathematics depend only upon In-

(*k*) I. Post Anal. c. 25.

duction or the constant Testimony of *Sense*. For first it may be noted, that if we ask any one, why he believes any Mathematical Axiom to be true, I imagine he will not answer, because he has often seen and observed it to have happened so; but he will profess himself ignorant of the Cause why he believes it, and yet that he firmly does believe it: Which is a plain Discovery that the Assent given to the Mathematical Axioms is some other Way derived than from the *Sense*. *Secondly*, It may be noted, that most Things in Mathematics, though the Occasion of contemplating them be taken from *Sense*, yet do not immediately and directly occur to the *Senses*, but their Existence and Quality is inferred and understood from the *Reason* alone. For who did ever see or perceive by the *Sense* an *exact Right Line* or a *perfect Circle*? Who at any time has had the *Sense* of any two Things compleatly agreeable or equal to one another? So far are we from finding the Attributes of these Things by *Sense*, or gathering the universal Propositions from thence wherein the Attributes are annexed to the Things. By Sensation indeed (*i. e.* by one, not many) may be deduced the Possibility of Mathematical Hypotheses: Thus *ex. gr.* we know that a Right Line can be drawn between two assigned Points; because we perceive by the *Sense*, how a Progress may be made from one Point to another, wherein if there be any Unevenness or Deflection, it can be so far rectified by the Hand as to make a Line *sensibly Right*; from whence we infer by our Reason, there being no Repugnance on the Part of the Thing, that all other Roughness and Exorbitances may be pared off and corrected, and so the Line become *perfectly Right*. And by the same Reason, one sensible Observation alone may sufficiently attest that every Magnitude treated of by Mathematicians is capable

capable of a real Existence ; and there is no need of a long Day to teach, but one only Discovery of Sense will abundantly evince, that all Mathematical Hypotheses are possible, that Magnitudes can be composed, divided, moved, fill Space, &c.

And here by the Way we may take notice of their Opinion who will have Mathematical Figures to have no other Existence in the Nature of Things than in the Mind alone. And it is wonderful to me that this Opinion should be embraced by Persons, who are otherwise most excellently skilled in the Mathematics: Among whom we may reckon (l) *Blancanus*, whose Words are these ; *Though Mathematical Beings have no real Existence, yet because their Ideas do exist both in the Divine and Human Mind, as the most exact Types of Things, therefore the Mathematician treats of those Ideas which of themselves are primarily intended, and are true Beings.* And of the same Sentiment is (m) *Vossius*. *There is not any Sphere* (says he) *in the Nature of Things that only touches in a Point ; for it always with some Part of its Superfice touches the subjected Plane in a Line, as* (n) *Aristotle shews Protagoras to have objected against the Geometricians.* Which Sentiment notwithstanding is absolutely false, and easy to be refuted from the foregoing *Discursus*, and what is most opposite to it seems, in my Opinion, to be most true ; viz. That all imaginable Geometrical Figures are really inherent in every Particle of Matter, I say really inherent in Fact and to the utmost Perfection, though not apparent to the Sense ; just as the Effigies of *Cæsar* lies hid under the unhewn Marble, and is no new Thing made by the Statuary, but only is discovered and brought to Sight by his

(l) Libro de Natura Mathem. p. 7.
de Mathem. p. 4.

(m) Vossius
(n) I. Metaph. cap. 2.

Workmanship, *i. e.* by removing the Parts of Matter which involve and overshadow it. Which made *Michael Angelus*, the most famous Carver, say, *That Sculpture was nothing else but a Purgation from Things superfluous. For take all that is superfluous (says he) from the Wood or Stone, and the rest will be the Figure you intend.* So if the Hand of an Angel (at least the Power of God) should think fit to polish any Particle of Matter without Vacuity, a Spherical Superfice would appear to the Eyes of a Figure exactly round; not as created anew, but as unveiled and laid open from the Disguises and Covers of its circumjacent Matter. Nay I will go farther and affirm that whatsoever we perceive with any Sense is really a Mathematical Figure, though for the most part irregular; for there is no Reason why irregular Figures should exist every where, and regular ones can exist nowhere. Moreover if it be supposed (*viz.*) that Mathematical Things cannot exist, there will also be an End of those Ideas or Types formed in the Mind, which will be no more than mere Dreams or the Idols of Things nowhere existing.

But having not Leisure to handle this Question more largely, let us again return from this Digression to our Enquiry concerning the Manner of attaining the certain Knowledge of Mathematical Axioms; about which we shall note, in the *third* and last Place; That the Truth of certain Propositions do neither appear from the immediate Intuition of the Mind, nor the frequent Observation of Sense nor yet from any supposed primary or original Notions, but is deduced by a certain implicit and as it were virtual *Discursus*, of kin to an intuitive Notion, either from the declared Signification of the Terms themselves, or from the supposed Generation of the Thing, which is manifestly possible and agreeable to the Suffrage of the Sense:
Which

Which seems to be the Case in most Mathematical Axioms.

Ex. gr. The Consequence seems to be sufficiently evident, *That a Whole is greater than its Part, or that a Part is lesser than its Whole*, from the proper Signification which is understood of the Words *Whole* and *Part*, *Greater* and *Lesser*. For by *greater than another* is denoted that which contains another, or has something beside what is equal to that other : by *lesser than another* is meant that which itself, or its equal, is so contained in another that something remains besides. But a *Whole* more strictly designs *that which contains another and something more* ; a *Part*, *that which is so contained in another, that if it be taken from that other something will remain over and above*. Whence it appears that *Greater* in respect of *Whole*, and *Lesser* in respect of *Part*, is, by the Signification of the Words, as the Genus to its Species, or as a more universal Term to one less universal, and consequently it is rightly predicated according to the infallible Rules of Logic, *that a Whole is a greater Thing, and a Part a lesser Thing*. (o) In the same Sort it will presently appear from the Notion of Equality, *That Magnitudes which are equal to the same Third are equal to one another*. As if, with *Apollonius* and certain others (p) that be supposed to design a Thing equal to another, which being compared with another will entirely agree with it, *i. e.* will fill the same Space and occupy the same Place ; from whence will follow the said Axiom by a peculiar Quickness with the most speedy Impulse of Mind, and as it were instantaneous *Discursus*. For supposing that any Magnitude A do fill the Place X, and moreover that the Magnitude B is equal to A, and because of the supposed

(o) Apud Proclum, p. 54.

(p) Hobb. in Philos.
Signification

Signification of Equality, does fill the same Place X ; also that the Magnitude C is equal to A, and consequently does in like Manner fill the Place X ; then because it is shewn that B and C do fill the same Place X, therefore B and C will be equal from the said presupposed Definition or Signification of Equality. The certain Knowledge indeed of that Axiom might depend upon such a *Discursus*, but the Mind discovers it with no Trouble, and as it were virtually rather than explicitly ; which *Discursus Proclus* blames that most famous Geometrician *Apollonius* for having invented, yet so that, were it worth the while, and Opportunity permitted, it seems no Difficulty to vindicate that great Man from Censure.

Whence it may be noted by the Way, that the Truth of most Axioms may be resolved into the Definitions or Explications of the Terms or Words whereby they are expressed (being gathered as *Po-rismata* from them by a certain easy and tacit Ratiocination) ; which Definitions Geometricians are yet wont to neglect by Reason of their too great Evidence : *The Signification, says (q) Aristotle, of taking equal Things from equals is not explained, because known.*

After the same Manner some Principles may be deduced by an implicit *Discursus*, from the supposed Generation of the Subject. As suppose a Circle to arise from the drawing about of a Right Line, one of its Extremes remaining fixed which is stiled the Center ; hence is immediately inferred that Axiom with scarce any Axiom at all of the Mind, *That all Right Lines drawn from the Center of a Circle to its Circumference are equal.* Also from the supposed Generation of a Right Line, we seem to gather (like Persons ignorant of it before)

(q) I. Anal. Post. c. 8.

that all Right Lines do intersect or cut one another in only one Point. As when the Right Line A B is indefinitely produced till it cut the Line E F, it can only cut it in the Point Æ . (FIG. II.) There is no need of learning these Principles any otherwise, than from the Definitions or Explications of the Words. But we have said enough in answer to the grand Argument by which our Adversaries endeavour to overthrow the Certitude of Mathematical Demonstrations; which Controversy I close up with the Words of *Lucullus* in *Cicero*. As the Scale of a Balance is depressed by imposing Weights into it, so must the Mind necessarily yield its Assent to Things clear in themselves.

But those who study to detract not from the Certitude and Evidence, but from the Dignity and Excellence of the Mathematics do bring another Device. For they attempt to prove that Mathematical Ratiocinations are not *Scientific*, *Casual* and *Perfect*, because the Science of a Thing signifies to know it by its Cause; according to that Saying of *Aristotle*; *We are supposed to know by Science, when we know the Cause*. And to use the Words of *Pererius*, who was no mean Peripatetic, *A Mathematician neither considers the Essence of Quantity, nor treats of its Affections, as they flow from such Essence, nor declares them by the proper Causes by which they are in Quantity, nor forms their Demonstrations from proper and essential, but from common and accidental Predicates*. Thus they. To which I answer, that those scientific Conditions, which *Aristotle* prefixes to Demonstration, who was most observant of its Laws, do most fitly agree with Mathematical Ratiocinations. For *first* he requires that the Premisses be *Universally* and *Necessarily true*: And what Necessity can be thought stronger, than that which Mathematical Axioms pretend to, whose Truth is eternal and unchangeable?

able? *Secondly*, he wills them to be *Primary* and *Immediate*, *i. e.* that they be proved by no precedent Argument, by no previous Notion: And who does not see that this agrees with the same Principles, which do not prove but assume Things, as self-convincing? *Thirdly*, he also directs them to be *More Known* and *More Evident* than the Conclusions inferred: But there is none who does not presently yield his Assent to these, as soon as they are heard and understood by him; and they are also more known than the Conclusions deduced from them, because, if we use a lawful *Discursus* the Truth of these appears by them. *Lastly*, he demands them to be the *Causes* of their Conclusions; which last Condition may be accepted two Ways: Either *first* only as they contain the Reason which necessarily causes the Conclusions to be believed as true, and produces a certain Assent, *i. e.* as the mean Term assumed obtains a necessary Connection with the Terms entering the Conclusion; whence arises that which is called a *Demonstration τὸ ὄτι that a Thing is*: or *secondly* more strictly, as this mean Term applied is more than a necessary Effect and certain Sign, *i. e.* as it is a proper Cause of the Attribute or Property, which is predicated of the Subject in the Conclusion; and hence is that called a *Causal Demonstration*, or a *Demonstration τὸ διότι why a Thing is*. But there is no Reason to doubt, but the last Condition understood in the former Sense agrees with the Premises of every Mathematical Syllogism, since there are no such Syllogisms, which do not most strongly compel the Assent; nor does this follow because the Premises are necessarily true (for otherwise they are not admitted by Mathematicians), but this Necessity argues that there is an essential Connection and Causal Dependence of the Terms between themselves in which it is founded, because the Ac-

cidents may be separated, and consequently the accidental Predicates are only attributed to the Subject contingently. (r) *Things Essential* (says Aristotle) are necessarily in every Genus, but *Things Accidental* are not necessary: And every such kind of Argumentation begetting a lesser Degree of Science is reckoned a more low and ignoble Demonstration, because it shews a Thing to be so only from its Effect or Sign, not from its Cause; but yet this most clearly convinces the Mind, and most validly confirms the Truth. There is therefore no Mathematical *Discursus* which proceeds not thus far. But that the foresaid Condition taken in the latter Sense does also agree with many Mathematical Ratiocinations, *i. e.* that the mean Term assumed in them has the Force of a Cause in Respect of the Property attributed to the Subject in the Conclusion, Aristotle is our first Author: He who, as has been just now said, most accurately knew and treated largely of the Nature of Demonstration, and consequently whose Authority is of the greatest Weight in this Affair; he, I say, fetches his most clear and strong, and perhaps his only Examples of Causal Demonstrations from Mathematical Disciplines. *Ex. gr.* he brings that celebrated Theorem, wherein it is demonstrated that the Angle in a Semicircle is a Right one, (s) for an Instance of a Demonstration from the Cause both material and formal. (t) And comparing the Mixed or Physico-Mathematical Sciences, which he calls Sensible, with the Pure, he says thus, To know that a Thing is, belongs indeed to such as are conversant in the sensible Sciences, but to understand why a Thing is pertains to those that are skilled in the Pure. (u) And again, speaking concerning Syl-

(r) I. Post. c. 6.
c. 10.

(s) II. Post. c. 11.

(t) I. Post.

(u) I. Post. c. 11.

logisms of the first Figure. *The Mathematical Sciences* (says he) *conclude their Demonstrations in this Figure, and in brief all Sciences that enquire why a Thing is.* Where he supposes the *Demonstrations* of Mathematics to be especially *Causal*.

But setting all Authority aside to come to the Truth of the Matter, it seems plain that *Mathematical Demonstrations* are eminently *Causal*, from whence, because they only fetch their Conclusions from Axioms which exhibit the principal and most universal Affections of all Quantities, and from Definitions which declare the constitutive Generations and essential Passions of particular Magnitudes. From whence the Propositions that arise from such Principles supposed, must needs flow from the intimate *Essences* and *Causes* of the Things. But I would become too prolix and troublesome to your Patience, if I should now go about to explain more distinctly how *Causal Demonstrations* do arise from *Mathematical Principles*, and so finish the remaining Part of this Disquisition, I therefore reserve it till hereafter.

LECTURE VI.

Of the Causality of Mathematical Demonstration.

WE have treated in Part concerning the *Evidence* and *Certainty* of the Mathematics in the last Lecture; it now remains that we speak of their Dignity, and shew more distinctly that they are really *Scientific* and *Causal*, and after what Manner; also, that we answer the principal Objections, that our Adversaries bring against us.

As to what pertains to the Manner of *Causality* we may take notice with (*x*) *Aristotle* that there are three Things to be considered especially in every Demonstrative Science ; *viz.* 1st, The *Subject* whose necessary Affections or Properties it contemplates, investigates, or demonstrates. 2^{dly}, The *common Axioms* whereby it seeks and demonstrates the Affections concerning the *Subject*. 3^{dly}, The Affections themselves, which are to be demonstrated of the *Subject*. There is Nothing that occurs very observable concerning the *Subject* of Mathematical Demonstrations, unless, as we shall explain by and by, that it is always some Species of Magnitude which is specified, determined and differenced from others by some reciprocal Property ; *Ex. gr.* a Right Line, an Angle, a Triangle, a Circle, a Cube, a Sphere, &c. are Subjects of Mathematical Demonstrations.

But concerning the Affections to be demonstrated I observe that they are of two Kinds, *viz.* *Common* and *Proper*. Those are *Common* which agree with their Subject *necessarily*, but not *solely*, as being also capable of being truly attributed to other Subjects. Thus, it is the *Common Affection* of an *Isoceles Triangle* to have three Angles equal to two right ones ; of a *Square* to have four right Angles ; of the *Circumference* of a *Circle* to be cut by a *Right Line* only in two Points ; for it happens also to a *Scalene Triangle* to have three Angles equal to two right ones ; and to an *oblong Parallelogram* to have four right Angles ; and to innumerable *Curve Lines* besides the *Circumference* of a *Circle*, that they only can be cut in two Points by a *Right Line* ; and hence it is apparent that such Affections do not flow from the particular Nature of their Subject, but from some more universal Reason ; and that they agree not with it

(*x*) I. Post. c. 8.

immediately,

immediately, but as it is comprehended under some higher and more extensive Genus of Magnitude : Moreover such Affections being too extensive cannot enter the Definition of a particular Subject, nor suffice to determine it, nor can it follow that the Subject is supposed, from supposing them. But *proper Affections* are such as agree with their Subject both *necessarily* and *solely*, *i. e.* they do so reciprocate with their Subject, that if they be supposed, it is also supposed of Necessity. Thus it is the proper Affection of a *Circle* among all Figures *to have equal Radii*, and every Figure that emits *equal Radii* from the *Center* to the *Perimeter* or *Circumference* is a *Circle*. So also it agrees with the same Figure *that if any Point be assumed in the Diameter, and a Right Line be erected perpendicular to the said Diameter meeting the Circumference, the Square of the intercepted Line is equal to the Rectangle (or Product) of the Segments of the Diameter*, or which is all one, *the intercepted Line is a Mean Proportional between the Segments of the Diameter* : This, I say, agrees with a *Circle*, and to whatsoever Figure this agrees, that is a *Circle*. In like manner, it agrees with a *Circle* *that every two Right Lines that can be drawn from the Extremities of the Diameter to any Point in its Circumference will make a Right Angle* ; and reciprocally every Figure with which this Affection agrees will be a *Circle*. Thus again, it agrees interchangeably with *parallel Right Lines*, *that if they are indefinitely continued they can never meet* ; *that other Right Lines intersecting them do make the alternate Angles equal, or the external Angles equal to the internal ones, or the internal Angles equal to two right Angles* ; *that all intercepted Right Lines drawn at equal Angles are equal to one another* ; and *that equal intercepted Right Lines do make equal Angles*. From whence it appears, that the Subject is determined

and limited by any of these Affections, and consequently that any of these may be rightly supposed or assumed in defining the Subject, since they are connected together with such an essential, close and reciprocal Tie, that if any one be supposed, the rest must necessarily follow. These Things indeed are denied by *Aristotle*, who affirms, that there can be no more than one Definition of the same Thing; but notwithstanding, according to his own frequent and never enough to be commended Saying, *It is a pious Thing always to adhere to the Truth*. It appears also hence that these Affections, on the Part of the Thing, are by Nature of equal Order and Degree, and have no Dependence one upon another. Which is clearly confirmed from hence, because their Subject may be divers Ways generated in respect to them. *Ex. gr.* A Circle may not only be generated by the *Rotation of a Right Line*, but also by the *drawing of Perpendiculars*, by the *Affection of right Angles*, and as many other Ways, as it has such reciprocal Affections or Properties. And the same Reason holds for all other particular Magnitudes. But if any one such Affection be taken at pleasure before others for the Definition of its Subject, it so far supplies the Place of a Cause, in respect of the rest; because by the Intervention of it, as a Mean, the rest do necessarily follow and become known. As if a Circle be defined from the *Equality of its Radii*, it will thence be demonstrated, that any *Perpendicular Line*, intercepted between the *Diameter* and *Circumference*, is equal to the *Rectangle* of the *Segments* of the *Diameter*; and that the *Angles* in the *Semicircle* are *Right ones*, and consequently that *Equality of the Radii*, as to the Manner of our Discursus, will be the Original of these Affections. But if a Circle should be defined (as it may be) to be a *Figure endowed with such a Property that if a certain Right Line be assumed*

in it; and any Perpendicular be erected from that to the Perimeter of the Figure, the Square of such Perpendicular will equal the Rectangle of the Segments of that Right Line: Or if it be defined a Figure wherein, if a certain Right Line be taken, two Right Lines any how drawn from its Extremities to a Point in the Perimeter do make a right Angle; from either of the Definitions the foregoing Affection of the Equality of the Radii may be easily deduced and demonstrated, and consequently that Equality will be respectively, as the Effects of the said Affections, and the Knowledge of that will depend upon the Supposition of these. And in like manner if *Parallel Right Lines* be defined from the Equality of the alternate Angles made by a Right Line intersecting them, the remaining Properties of *Parallel Right Lines*, related above, will arise from thence. I deny not but some of these reciprocal Affections do seem more simple and evident, more obvious and manifestly possible, than others; as the *Equality of the Radii*, already mentioned, seems more easy and plain, than the other Properties of a *Circle*, because it is entirely deduced from a Generation by the Rotation of one of those *Radii*: And that negative Property seemed to *Euclid*, as the most easy and clear of all Properties belonging to *Parallel Lines*, that how far soever they be produced they can never meet; though he was not so right in this, as is thought by some; among whom, for many Reasons, I beg leave to subscribe my own name. I also acknowledge the Expedience of beginning an Argumentation, or of defining a Subject, from such Affections as are most easy and familiar, rather than from others; *ex. gr.* to define a *Circle* rather from the *Equality of its Radii*, than from that *Equality of a Square with a Rectangle*, which was just now mentioned. As to our Apprehension I allow the former the Preference,

though it is all one, as to the Nature of the Thing, from which the Discursus takes its Rise, for which soever Link of the Chain you take hold of, the Whole will follow; but we usually seize upon that which is most obvious and ready. It is here as in the Progress of a *Circle*, from whatsoever Point of the Circumference you take your Beginning, you will measure over the Whole. Such in Reality and no other is the mutual *Causality* and Dependence of the Terms of a *Mathematical Demonstration*, viz. a most close and intimate Connection of them one with another; which yet may be called a *formal Causality*, because the remaining Affections do result from that one Property, which is first assumed, as from a Form. Nor do I think there is any other *Causality* in the Nature of Things, wherein a necessary Consequence can be founded. Logicians do indeed boast of I do not know what kind of Demonstrations, from *external Causes* either *efficient* or *final*; but without being able to shew one genuine Example of any such; nay I imagine it impossible for them so to do. For there can be no such Connection of an *external, ex. gr. efficient Cause* with its *Effect*, (at least none such can be understood by us) through which, strictly speaking, the *Effect* is necessarily supposed by the Supposition of the *efficient Cause*; or any *determinate Cause* by the Supposition of the *Effect*. Nay there can be no efficient Cause in the Nature of Things of a philosophical Consideration which is altogether necessary. For every Action of an *efficient Cause*, as well as its consequent *Effect*, depends upon the *Free-Will* and Power of *Almighty God*, who can hinder the Influx and Efficacy of any *Cause* at his Pleasure; neither is there any *Effect* so confined to one *Cause*, but it may be produced by perhaps innumerable others. Hence it is possible that there may be such a *Cause* with-

out a *subsequent Effect*, or such an *Effect* and no peculiar *Cause* to afford any Thing to its Existence. There can therefore be no Argumentation from an efficient *Cause* to the *Effect*, or contrarily from an *Effect* to the *Cause*, which is lawfully necessary. *Ex. gr.* Because there is Fire it does not necessarily follow that there is Fuel for it to feed on, or Smoak sent from it; since History relates that, in Fact, it has happened otherwise. Neither, on the contrary, is the necessary Existence of Fire inferred from Ashes or Smoak. For who doubts but God can immediately create Ashes and Smoak, or produce it by other Means? Perhaps you will say, that Ashes and Smoak denote an intrinsecal Relation of Fire. I answer briefly, This supposes the Argumentation not to proceed from the *efficient Cause* or the *Effect*, but from the *formal Cause* or *Causate*; yet however a Thing of the same Nature and as some speak the same *Specifically*, as Ashes or Smoak, can exist without the Efficacy of Fire, and take its Rise from other Causes, which makes for our Purpose. Nor does the Astronomer, from the Height of the Sun, wholly demonstrate its Continuance above the Horizon, or the past Time of the Day: For we read of the Sun's having once been fixed in Heaven, and another Time of its going backwards. In like manner from that most celebrated and trite Example of a Demonstration from the *efficient Cause* (which is used by *Aristotle*, and other Writers of Logic) of the Earth's Interposition between the Sun and Moon, it does not follow that the Moon undergoes an Eclipse; for, if God please, the solar Rays may pass through the Body of the Earth, or reach the Moon by an indirect Passage without touching the Earth; or otherwise the Moon may be enlightened some other Way: Nay the Sun itself does not infer Light; for at the Death of our Lord,
the

the Setting of the better Light of the World, the Sun as if struck with Fear and confounded with Shame, drew in his Rays, and hid his Face, and even at Noon-day suffered an Eclipse, without any Moon to intercept his Light, or any Cloud to darken his Brightness. A Defect of Light then cannot be concluded from the Interposition of an opaque Body, nor this from that. I own according to the Law and Custom of Nature, that such Effects do always proceed from such Causes; and therefore we may pardon *Aristotle* for supposing Nature subject to an intrinsic Necessity, and not obnoxious to an external superiour Power: but in reality it is one thing to happen naturally, and another to exist of Necessity. For necessary Propositions have an universal, immutable and eternal Truth, subject to nothing, nor to be hindered by any Power. *Science* (says (y) *Aristotle*) is comprehended of Necessity, whence it is that it is eternal: For all these Things that are simply necessary are eternal. Again. (z) The Conclusion of a Demonstration must be eternal. Because therefore the Efficacy of Agents may be stopped, or changed, and every Effect may proceed from various Causes, there can be no Demonstration from an efficient Cause, or from an Effect. And the same Reason holds of a final Cause and its correspondent Means, i. e. no determinate Means will follow from the End, nor will the End necessarily follow from the Means. We have nothing then to wonder at, that there are no Demonstrations in Geometry drawn from an efficient or final Cause, but do all proceed from the Form and inward Constitution of the Thing expressed by the Definition. They are therefore to be blamed, who require such Demonstrations

(y) VI. Eth. c. 3.

(z) I. Anal. Post. c. 7.

from

from Mathematicians, as themselves never saw or dreamed of.

From what has been said it follows that the Syllogism in which one essential Affection is connected with, or inferred from another, is a *Causal Demonstration*, *i. e.* one deduced from a *formal Cause*: And such a Syllogism, *ex. gr.* is the following one. *In every Figure having equal Radii, the Square of a Perpendicular is equal to the Rectangle of the Segments of the Diameter: The Figure Z has equal Radii (viz. by Hypothesis, or what already appears): Therefore in the Figure Z, the Square of a Perpendicular is equal to the Rectangle of the Segments of the Diameter.* Here a certain Affection, *viz. the Equality of a Square with a Rectangle* is demonstrated of the Figure subjected, by an *Equality of the Radii*; which, in respect of that, is a *formal Cause*, as was shewn above. Such also is this Syllogism. *Right Lines never meeting, if intersected by a Right Line, do make the alternate Angles equal: But the Right Lines A, B, (by Hypothesis, or what has been demonstrated) do never meet one another; therefore a Right Line intersecting the Right Lines A and B, makes the alternate Angles equal.* And this may suffice concerning the Affections to be demonstrated.

As to *Axioms*, I observe, that they either agree universally to all Quantities, *viz. all Lines, Superficies, Solids, and Angles*, and by Reason of these to Numbers, Weights, Times, and all other secondary Quantities; or particularly to particular Quantities: Those may be named *Universal*, these *Particular*. *Universal Axioms* declare certain essential Affections of all Quantities, so simple and clear that they can scarce by Hypothesis be demonstrated by others prior to them, at least they need no Demonstration. Thus it agrees absolutely with all Quantities, and may be pronounced of them in

general, *That Quantity is divisible into homogeneous Quantities, i. e. a Line into Lines, a Superfice into Superficies, a Body into Bodies : That homogeneous Quantities may be compounded or added to one another : That a lesser Quantity may be subducted from a greater : That every Magnitude does fill a Space adequate to itself : And that every Magnitude is capable of a determinate Situation ; can rest ; can be moved with any Motion, direct or circular, uniform or ununiform, swift or slow.* Indeed such *absolute Axioms* are not mentioned by Geometricians, by Reason of their too great Evidence, but they ought to be understood, because of other *Axioms*, and for the sake of the Definitions of particular Magnitudes, and all kinds of Hypotheses. *Ex. gr.* When it is said *Magnitudes, which are congruous to one another, or which fill the same Space, are equal ;* it is supposed, as a thing possible, for Magnitudes to fill Space. When a *Right Angle* is defined from such a Position of one *Right Line* upon another ; it is supposed a thing possible, for a *Right Line* to obtain such a Position. When a *Circle* is defined from the *Rotation of a Right Line*, that *Rotation or Motion* is taken as possible to be done. And to Quantities compared together may be attributed such Affections as these, *viz.* the Equality of two Quantities following their Equalities to a third ; the Equality resulting from Congruence, or the Completion of the same Space ; the Equality arising from the Composition or Division, the Addition or Subtraction of Equals ; and such like. The same Way do Affections (which because of their Simplicity and Evidence either cannot, or need not, be demonstrated) express the *particular Axioms* belonging to particular Quantities. As *ex. gr.* It is the Property of a *Right Line*, that it can only be intersected by another *Right Line* in one Point ; that it has no Part common
with

with another *Right Line*; that it cannot include *Space*, or constitute a *Figure* with another *Right Line*. It also agrees with it, that it can lie between any two assigned *Points*; that it may be infinitely, or indefinitely produced; that it may be the *Radius* of a *Circle*. These are Things required by Geometricians, but may be boldly pronounced, being Affections of a *Right Line*, and easily deducible from its Definition, whatsoever it be. Which *Axioms* may perhaps be capable of Demonstration, as I have said above; but because their Truth is most easily perceived and granted, it is neither necessary, nor expedient to be done. Since therefore these *Axioms* do contain Affections essential either to all *Quantities*, or at least to some particular ones; and since they necessarily agree together (I mean some respectively with some) it is apparent that they are rightly applied to Demonstration, and that *causal Demonstrations* may be made from them. Take an Example in the following Syllogism; *Those Things which are congruous to one another, are equal to the same Thing: The Magnitudes A and B are congruous* (by Hypothesis, or what is proved before) *therefore the Magnitudes A and B are equal to the same.* Where the Equality of two Magnitudes in respect of the same, is deduced from its *formal Cause*, viz. from the Congruity of these Magnitudes. But at present I will add no more concerning *Axioms*, only I affirm, that since all *Mathematical Theorems* are derived from these, i. e. from the *general Affections* of all Magnitudes, and from the *reciprocal Properties* of particular Magnitudes, it sufficiently appears, that they are demonstrated from their *Causes*: It is therefore meet that I proceed to what remains of the Disputation I have undertaken against the Impugners of *Mathematical Demonstration*, and consider briefly the *Instances* they bring against it.

First,

First, They aim at the very Head of Geometry, and deny that the Proof of the very first Proposition of the Elements is deduced from proper Causes, and therefore is not demonstrated by the best Reason : For they say it is there inferred, that a Triangle will be Equilateral from hence, because it may be constructed between two equal Circles, which agrees not with an Equilateral Triangle essentially, but accidentally ; because it will be Equilateral, though these Circles were not drawn at all, or were entirely wanting. To this Instance and such like it is differently answered by different Persons, though indeed appositely enough by all. I shall pass by the Answers of others, and shall give an Answer of my own, without borrowing any thing. And first I shall take notice, that the word *Demonstration* is taken many Ways. As *1st*, For any particular scientific Syllogism, according to *Aristotle's* Definition, *A Demonstration is a Syllogism producing Science* ; this may be termed *Simple Demonstration*. *2dly*, For a System of more such Syllogisms connected together in a certain Series, and conspiring together for the Proof of one Proposition ; which Sort may not unfitly be named *Compound Demonstration*. *3dly*, For the ultimate Syllogism, whereby the proposed Conclusion is immediately confirmed, to which the other Syllogisms do all aim and conduce : Which being supposed, I observe that if the particular Syllogisms of a *Compound Demonstration* be all *Causal*, especially the last, by which is given as it were the finishing Stroke ; then the whole *Compound Demonstration* deservedly ought also to be reckoned *Causal* and *Scientific*. Moreover I take notice, that certain Things assumed or proved may, in the Course of the whole Demonstration, seem accidental in respect of some one (*ex. gr.* the Ultimate) Conclusion, which yet in Respect of others may be proper and essential ;

essential; nor is there any need for all the Prædicates in the Series of a *Compound Demonstration* to agree essentially with the Subject of the finishing Conclusion; but it suffices for every Thing so to agree with the Subject of its proper Conclusion. From which Observations most or all the Instances brought against Mathematical Demonstrations may be overthrown. And consequently, if the particular Syllogisms (brought either for the Construction, or Demonstration of the abovesaid first Proposition of the Elements) be *Demonstrations* simply *scientific*, the Proposition ought to be reckoned as *scientifically demonstrated*. We will therefore examine them; but for brevity's sake, we will substitute *Enthymems* for Syllogisms, and insinuate the Necessity of the Consequence. A Proposition (which I imagine unknown to none of you) is as follows.

Upon any given Right Line A B to make an Equilateral Triangle; or which is all one, if we reduce this Proposition to the Form of a Theorem (since every possible Problem may be taken for a Theorem, as far as that Possibility is demonstrable) it will be as follows. An Equilateral Triangle is possible to be made upon any given Right Line A B. (FIG. III.)

CONSTRUCTION.

1. Enthymeme. *Any Right Line may be the Radius of a Circle. Therefore A B is the Radius of a Circle, whose Center is A.*

The Antecedent contains the essential Property of a Right Line, as is remarked above.

2. Enth. *By the same Reason, with the Center B and Interval A, a Circle may be described. Let therefore the Circles B C D, A C E, be supposed to be drawn, because it is shewn that it may be done.*

3. Enth.

3. Enth. *Two equal Circles described by a common Radius will mutually intersect each other : Therefore the Circles B C D and A C E will intersect each other : suppose in the Point C.*

The Antecedent is manifest from that most evident Property of a Circle, that it is on every Side inclosed and terminated.

4. Enth. *A Right Line may be drawn from one given Point to another. Therefore the Right Line A C may be drawn from A to C.*

The Antecedent is the Property of a Right Line, as we have said before. *Let A C therefore be drawn, because it may be done.*

5. Enth. *By a like Reason may be drawn the Right Line B C. Let it therefore be drawn.* Now it is plain, that a Triangle A C B is here constituted from the Definition and Nature of a Triangle : And the Construction of the Problem is finished. It next remains to be demonstrated that the Triangle A C B is equilateral, and what follows may be converted into this Theorem.

A Triangle made of Right Lines drawn from the Centers of two equal Circles, described by a common Radius to the Intersection of these Circles, is equilateral.

The following Enthymemes do serve for the Demonstration of this Theorem.

1. *Right Lines drawn from the Circumference of a Circle to its Center are equal to one another. Therefore the Right Lines A C and A B are equal.* The most noted Property of a Circle whereby it is defined is in the Antecedent.
2. *By the same Reason the Right Lines B C and A B are equal.*
3. *Those Things which are equal to the same Third are equal to one another. Therefore the Right Lines A C and B C are equal to one another, because they are proved to be equal to the same*
Line

Line A B. The Antecedent is the most evident and noble Property of Magnitudes compared, of which it was spoke above.

4. The ultimate and decretory Syllogism follows, which finishes the Whole. *Every Triangle which has three equal Sides is Equilateral. The Triangle A B C, from what is just now demonstrated, has three equal Sides. Therefore the Triangle A B C is Equilateral.* The major Proposition is the Definition of an Equilateral Triangle; and the *Cause* of the Conclusion is most evidently contained in the Premisses. For I cannot imagine what *Cause* can be supposed more near and intimate, why the Triangle A B C is Equilateral, than this, *that it has three equal Sides.*

We have seen then, that all the Syllogisms of this Proposition, which serve both for its Construction, and the Demonstration of that Construction, are so many true Demonstrations, as being deduced from the essential Attributes of the Things subjected; the last especially being in the highest Degree *Causal* and *Scientific*. I hope then enough has been done for this Instance.

But as I remember *Pererius*, and others, do produce another Instance, also blaming that celebrated Proposition which is the thirty-second of the first Element, as not scientifically demonstrated. For they say that here also, to demonstrate that all the Angles of a Triangle are equal to two right ones, one Side is produced, and a Parallel drawn to another; the Possibility of which Performance is entirely extrinsecal and accidental to the Thing proposed; nor has the Equality of the Angles in the Triangle, the Thing to be proved, any Dependence upon it. Therefore it does not follow from hence that this Demonstration is *Essential* or *Scientific*. These most subtle, or rather captious Dis-

H putants,

putants, if I mistake not the Matter, require Conclusions without any *mean* or middle Term found or assumed for their Deduction, or which is the same, demand an Argumentation without an Argument. *Aristotle* does indeed reject *Heterogeneous Arguments*, *i. e.* such as are drawn from Sciences of another Nature; but these Men seem to reject all Arguments, expecting a Thing should be proved of itself, without suffering any Thing to be granted. But to come to the Business. 1. *Aristotle* brings this very Proposition for an Example of those Things that are essentially inherent to their Subject, and causally demonstrated. (a) *We know* (says he) *essentially and not accidentally, when we understand something so to agree with another, as it does agree in Reality, and that by Principles proper to it. Thus we know the Property of having three Angles equal to two right ones, when we understand that to which it agrees by Reason of itself, and consequently we know by the Principles which properly belong to that Thing.* 2. I briefly reply, because a Triangle is constituted of Right Lines, the Properties of a Right Line do so far pertain to it. But it is the Property of a Right Line that it may be produced; therefore this Production is not altogether accidental or extrinsecal to a Triangle. In like manner it is also the Property of a Right Line, as was before demonstrated, that another Right Line may be drawn parallel to it through any Point without itself. Therefore this also agrees essentially with a Triangle, as far as Right Lines (*i. e.* its Sides) do enter its Constitution. Moreover, 3. I imagine our Adversaries do not deny the Truth of that Proposition, nor therefore that it may be demonstrated. Therefore some *Mean* ought to be assumed for demonstrating it. An external Angle

(a) I. Post. Anal. cap. 7.

is assumed and shewn to be divisible into two Parts equal to the two internal and opposite Angles of a Triangle; whence it most evidently follows that all the internal Angles are equal to two right ones. And I do not see that any *Mean* can possibly be assumed more convenient, or more intimate than this. Again, 4. I here answer as in the former Instance. If the particular Syllogisms are examined, from which the Demonstration of this thirty-second Proposition is taken, it will be found that their whole Force depends either immediately or mediately upon Definitions or universal Axioms. From whence it will appear that these Demonstrations are *Scientific*; and consequently so is the whole Demonstration made up of them, and the ultimate Syllogism whereby the Proposition is immediately demonstrated. After the same manner may easily be answered all the Instances that can be brought.

That I may at length finish this somewhat long, and I fear disorderly Dissertation, because too hastily composed and delivered; it seems to me that every certain and evident Discursus, flowing according to the irrefragable Rules of Logic, from Principles universally and perpetually true, and consequently wherein a necessary Connection of the Terms is found, is most properly, scientifically and perfectly a Demonstration: And that all other *Causality*, which is here applicable, besides this Connection already explained, is mere Fiction, supported by no Argument, nor confirmed by any Example: And that Demonstrations, though some do outdo others in Brevity, Elegance, Proximity to their first Principles, and the like Excellencies, yet are all alike in Evidence, Certitude, Necessity, and the essential Connection and mutual Dependence of the Terms one with another. Lastly, that Mathematical Ratiocinations are the most perfect Demonstrations.

I had indeed explained these Things somewhat more fully and largely, if some little Business intervening had not disturbed my Thoughts, and shortened my Time for Study; and if a Kind of Illness, not indeed very grievous, but yet troublesome, had not seized me for some Days. Therefore I beg to take my Leave of you for the present Season, wishing that Health to you which I cannot enjoy myself.

Here ended the first Year after the Institution of this Professorship, which happened to have only one Term. I have borrowed the two first Lectures of the following Year, to encrease the Number, and fill up the Paper that remains here.

L E C T U R E VII.

Of the Nature of First Principles.

IT is a Custom very agreeable with good Manners, and I believe no where more confirmed by frequent Practice than among yourselves, for Friends that meet together after a long Absence to embrace with a more ardent Affection, and address one another with a more liberal Conversation. In compliance with which Custom to Day, if Nature had bestowed, or Art procured for me but a moderate Faculty of speaking, I confess indeed very many Things might be pertinently urged. For I am pushed on with the truest Incentives of a most hearty Affection, and instructed with the most splendid as well as copious Argument of Speech, to return due Thanks for your singular Benevolence experienced upon myself, to set forth your diligent Study bestowed upon the liberal Sciences, and to applaud
and

and congratulate your Patience such as is becoming Philosophers. But since both my own Disposition is very unmeet and averſe to Oratory, as well as in ſome Meaſure the Reaſon of my Office; and ſince you yourſelves, I imagine, do not come hither to have your Ears tickled with rhetorical Compliments, but to compoſe your Minds to the Severity of Philoſophy; not ſo much deſiring to hear Speeches made to you, as to have the Science of Things explained to you: I will therefore reſtrain my Tongue from breaking out into pathetic Excuſions; and wholly omit every kind of Preface. Only give me leave, moſt courteous Auditors, officiouſly to embrace you with the Arms of Gratitude and Benevolence, heartily wiſhing you all Health, and praying that our meeting together again may be delightful and auſpicious. And ſo, without more ado, I apply myſelf to the Work of my Office, propoſing now to purſue what I left the laſt Term, and endeavour to finiſh what was then begun.

Be pleaſed then to recollect what I at that Time propoſed to treat of, and how far I proceeded. I undertook to erect an Entrance preparatory to the Diſciplines I was engaged to treat upon, *i. e.* to handle certain Things which are neceſſary to be premiſed concerning the Mathematics. And this I did by treating largely, *1ſt*, concerning their *Name*, ſhewing why they obtained the Title of Diſciplines after a peculiar Manner to themſelves. *2dly*, Concerning their *general Object*, how far it extends itſelf. And, *3dly*, Concerning their *Division*, as well according to my own, as the Sentiments of others. Next I began to treat concerning the *Manner* whereby they are converſant about their Object, *i. e.* the Invention and Aſſertion of the Properties agreeing with their Object, by a certain and evident Diſcuſus or Argumentation, which is wont

to be denoted by the Name of *Demonstration*: Whose Nature I endeavoured to illustrate from the Difference between the Mathematical Way of arguing, and that which is used in most other Sciences, by a diligent Comparison of both; assaying afterwards to vindicate the *Certitude* and *Excellence* of Mathematical Argumentations, as much as was requisite from the Inferences and Tricks of Adversaries.

These Things being discussed according to my Ability, the next thing should be (and my Mind inclines me so to do) to come to the Explanation of the *Species* or Kinds of *Mathematical Demonstration*, and treat also of *Mathematical Invention*, a most noble Subject, if it did not seem necessary first, to consider the integral Parts of a Mathematical Syllogism, *i. e.* to enquire concerning the Premisses of every *Mathematical Discursus*, what Sort they are, and how divided.

As to what pertains to the Premisses of every *scientific Discursus*, these are either *first Principles*, or *Conclusions* derived in a continued Series from *first Principles*, which after they are so derived, have themselves the Force, and are in the Room of *Principles*, in respect of the *Conclusions* which may be inferred from them, or proved by their Help. For the whole Force of any *Demonstrative Ratiocination* is resolved into the *Certitude* and *Evidence* of the *first Principles*: All the Truth, the Validity, and Evidence of every Science adheres to these inseparable Roots, and depends upon these unshaken Foundations. Wherefore we will first of all treat of these, in a few Words more generally concerning the Nature of Principles; then concerning their Differences; and lastly, concerning their different Species separately.

As to what pertains to *Principles universally*, *Aristotle* in more than one Place rightly observes, that

that as there is no Progress in natural Motion from Infinity or to Infinity, but there must be a Beginning from some Term, to end at some Term, since Infinity cannot be passed over, (*i. e.* if a Progress be assumed from Infinity, it will never end here, nor will a Progress tending from hence to Infinity, ever end any where): So in the discursive Operation of the Mind, which is like a Motion continually successive, there ought to be some appointed Bound for the Discursus to take its Beginning from, *i. e.* all Propositions are not to be proved by others in a continual Series, but some ought to be assumed by him that demonstrates, and granted by him that hears; otherwise every Examination, Confirmation, or Declaration of the Truth, which is undertaken, will be endless and vain. As no House can be built, so no Science can be erected but upon some Foundations. Such Propositions therefore are termed *Principles*, because from these (which are assumed *gratis* and willingly granted, as it were by the mutual Consent and Agreement of the Teacher and Learner) the Argumentation takes its Beginning, proceeding from thence to Things more remote. They are therefore defined by *Aristotle*, *Immediate Propositions*, because they are supported by no *Mean* or Argument from something else; or because Assent is given to them immediately, and at once, without mediate Reasoning. Which is not so to be taken as if *Principles* were required to be simply indemonstrable, and can no way be demonstrated or proved; for thus very few or no Axioms of any particular Science can be called or accounted Principles. For I doubt very much, or rather am inclined to believe, that, except that one only Foundation of all Reasoning, *That contradictory Propositions cannot be both true or both false*, no other Axiom is simply demonstrable. I say Axioms, for concerning Definitions and Hypotheses

potheses the Case is somewhat different, as we shall see by and by, which yet may be proved or illustrated after their own Way. However the *Principles* of a particular Science not only may, but ought to be demonstrated by the Master, if the Scholar requires it. For the Teacher of a Science is bound by his Office, if he desire to discharge it faithfully and answer his Character, to take away all reasonable Scruple from the Student; therefore if the Principles which he assumes be obscure, they are to be illustrated with Examples; if doubtful, they are to be confirmed from other Principles more known and indubitable, by prolonging the Discursus, if need be, and the Student require it, even to the very first Principles of all. *Ex. gr.* If any one doubt that *Principle* in Optics, *That the Species of a visible Point is carried or irradiated directly to every Point of the circumjacent Medium*; it is hence confirmed, because we experience, that an objected Point may be beheld by every Situation of the Eye, except an opaque Body be somewhere interposed in a Right Line from the visible Point to the Eye. And indeed most Theorems of Geometry are *Principles* in respect of Optics, Mechanics, Astronomy and other Parts of Mathematics, *i. e.* they are supposed as Truths in them, without any Demonstration at all. But if the Truth of any Theorem be not apparent to the Student, it is incumbent upon the Optician (or Master of any other Science) to demonstrate it, or at least to shew where it may be found demonstrated. Nay if he hesitate at any Geometrical Axiom, the Teacher cannot in Reason avoid the Necessity of demonstrating it: For no Demonstration can be reckoned accurately perfect, and strictly scientific, which reaches not the original Fountains of Science, even to some thing simply indemonstrable, confirmed by its own Force, and evident from its own Light. *For then only* (says
the

the Philosopher) *we are supposed to know a Thing, when we know its first Causes and Principles, even to the very first Elements.*

But some will ask, How can the Truth of Geometrical Axioms be demonstrated? I will answer, by other Axioms more simple, if any such there are, which are to be drawn from some higher and more universal Science, as *Metaphysics*; I say *Metaphysics* which is, or ought to be, the Treasure of the most general and simple Notions; and is therefore by (b) *Aristotle* named the *Mistress of all Sciences*; by *Proclus*, *The one shoeless Science from which others receive their Principles.* But if, by the Definition of the Terms of the Axiom proposed there appear no Axioms more Simple; as if any one should doubt whether the Whole be greater than its Part; if no Theorem or Axiom in *Metaphysics* can be found more certain, more evident, more simple than this, by which it may be demonstrated, we are to have Recourse to the Definitions of a *Whole* and a *Part*, *Greater* and *Lesser*; from the right Position of which, it will not be difficult to demonstrate that Axiom. And the same Reason holds in others. Whence also it appears, that it pertains not to the Nature of Principles, nor is required of them, that they appear necessarily true in themselves, or immediately evident to every Capacity; but only to him who comes ready and prepared for learning that particular Science, to which the said Principles are subservient, *i. e.* to the studious and teachable Mind. *Ex. gr.* The Theorems of Geometry which (as was just now said) do acquire the Place of *Principles* in Optics or Astronomy, are more manifest to one skilled in Geometry, and do most easily command his Assent; but are hard to be conceived and yielded to,

(b) *Anal. Post. I. 9.*

by one ignorant of that Science ; yet they do not therefore cease to be *Principles* belonging to those Disciplines : at least it follows from thence, that he who is no Geometrician is an unfit Person to learn them. *Aristotle* therefore teaches wisely and circumspectly, that Demonstration proceeds not absolutely from Things manifest, but only in such sort, that the Things admitted do draw their Conclusion after them, overspreading it with their Light, if any they have. The *Principles* therefore of no particular Science are necessarily and simply self-evident or indemonstrable, but only ought to be credible and sufficiently manifest to a well prepared Hearer. (c) *Proclus* argues not ill to this Purpose. *No Science* (says he) *demonstrates its own Principles, nor makes any Dispute about them, but looks upon them as self-evident ; and afterwards they are more conspicuous.* And *Aristotle* himself, *I call also them Principles in any particular Science, which cannot be demonstrated, i. e.* cannot be demonstrated in a particular Science, otherwise they would not be *Principles* ; but perhaps some of them both can and ought to be demonstrated without it. Again (d) *Aristotle* intimates that a Geometrician as such, lays not down his Principles, nor converses with that Science where it fails him ; but has Regard to some other Science ; and, where all others fail, has at last Recourse to the Science which is common to all others, *viz. Metaphysics.*

But according to *Aristotle* the primary Condition of Principles is, that they be universally and necessarily true, *i. e.* do suffer no Exception of Place, Time or Chance ; and it is repugnant to the Nature of a Subject for the Predicate not to agree with it. Otherwise the Conclusions inferred would become false and uncertain, and not a certain and

(c) Lib. 2. p. 22.

(d) *Phyf.* I. 2.

firm Science, such as is expected from Demonstration, but Error or a doubtful Suspicion would be produced. For in every scientific Syllogism consisting of one or more immediate *Principles*, the *Principle* assumed is the Major Proposition in the first Figure; and therefore unless it be universally true, there can be no Argumentation, as is well known in Logics. And if there be any Weakness or Imperfection of the *Principles* (such especially as *Particularity* and *Contingence*) it will be necessarily derived upon the Conclusions. Nevertheless it may be of Use about this *Verity* of *Principles*, to take heed that it be not of one Genus nor altogether Univocal. For the *Verity* of that *first Principle* concerning the impossible Coexistence of Contradictory Propositions as to Truth or Falshood, does seem to differ, as it were, in Specie from the *Verity* of all other *Principles*. For with respect to its Origin, whatsoever it may be concerning others, this Notion at least does seem to be immediately connate with our Minds, and implanted in us by God, together with the Faculty of Reasoning to which it is intrinsically annexed. For there can be no Reasoning without the Admission of this Principle, nay all Ratiocination tends to this, to this it is reduced; so that the Adversary is compelled to contradict himself by admitting the greatest of all Absurdities that Contradictory Propositions may be both true. If this be not granted, all Reason, all Disquisition or Disputation about Truth is entirely vain and insignificant. This depends upon no other previous Notion, Supposition or Argumentation, but is included in all Reasonings, as the Foundation upon which they are built, and the Instrument whereby we are rendered capable to reason about other Things. Therefore this Principle seems to be eminently true above others. (e) *Where-*

(e) *Metaph.* III. 3. & XI. 7.

fore all Demonstrations (says Aristotle) are reduced to this Notion. For this is by Nature the Principle of all other Axioms.

Although in Strictness, because a valid Syllogism should walk upon two Legs, and it is not sufficient for only one of the Premisses to be undoubtedly true, it is perhaps necessary, that one or two Axioms ought to be required as preparatory to all Reasonings; viz. these, *That Sense in its own Way is an undoubted Criterion of Truth, or that the Appearance of a Thing is a certain Discovery of its Existence.* Also *that the Possibility of a Thing is argued from the Existence of its Like; or that from an entire Parity of Reason a Consequence may be drawn of a Possibility of Existence.* For all Science, all Argumentation seems to depend upon a tacit Supposition of these. Since no other Truth of other indemonstrable Principles does seem to be required besides a sufficiently manifest Possibility of the Conception which is formed in the Mind, concerning the Existence of some Property; *i. e.* that we conceive and suppose something to be done, which really may be done. As *ex. gr.* when we suppose that two Things may fill the same Space, be congruent with one another, or coextended: That a Right Line may be drawn between two Points: That a Right Line may be turned about with one of its Extremes at rest, till it come to its first Position: That the Earth may be interposed in the same Right Line between the Sun and Moon: Because there is Nothing impossible or inconsistent contained in these Positions or Conceptions; therefore these are called *Hypotheses*, and ought to be granted as true. And their Truth is nothing else but the possible Connection of a Subject with its Predicate, which we clearly perceive, but perhaps cannot otherwise prove, but by a similar Example or Experiment,
i. e. by

i. e. by Help of the *Principles*, which, we have just now said, do seem to be subjunct to the first Principle concerning Contradictories: For perhaps we apprehend that and that only, as possible, of which we have in some sort experienced the same in Specie, or something very like it. In like manner the Falshood of any *Hypothesis* seems to be nothing but the Conception or Position of a Thing as effected or existing, which cannot be effected or exist. As if one suppose a rectilinear Triangle to be Quadrangular; a Body to be indivisible; or a Man to be void of Sense and Reason; if a Square be required to be made or supposed to exist with its Diameter commensurate to its Sides; a Triangle two of whose Sides are equal to the third; or a Circle whose Circumference is four times its Diameter: Since it is repugnant for these Things to exist, at least since never the like has at any Time occurred to the Mind, or the Experience, it follows that all such Propositions ought to be repudiated, and not admitted into the List of *Principles*.

From which Observations it seems to follow, that every *Demonstration*, to make it effectually such, does in some sort suppose the Existence of God; not only on the Part of the knowing Power or Faculty, but also on the Part of the knowable Object. *Cartesius* has very well observed, that to make us absolutely certain of our having attained the Truth, it is required to be known whether our Faculties of apprehending and judging the Truth be true, which can only be had from the Power, Goodness, and Truth of our Creator. But because also the Truth of indemonstrable Principles depends, on the Part of the Object, upon the possible Existence or Effectation of the Things supposed; and all Possibility intrinsically denotes a Respect to the Cause or Power by which the

Things do exist, which are called or conceived to be possible; therefore a Demonstration supposes the Power which effecteth all Things that are conceived or supposed under the Notion of Possibles, *i. e.* the infinite and incomprehensible Power of God, which can produce whatsoever Effects we are able to conceive as possible, and innumerable other beyond our Comprehension. Every Demonstration, I say, supposes true Hypotheses; the Truth of an Hypothesis intimates the possible Existence of the Thing supposed; this Possibility denotes the efficient Cause of the Thing (since otherwise it would be impossible for it to exist); and the efficient Cause of all Things is God. But I will not pursue this Digression any farther.

Hence also it follows, that Demonstrations may be made of Things, which never had Existence any where; because it is sufficient for a Demonstration to assume true Hypotheses, *i. e.* such as imply no Inconsistence in themselves. *Ex. gr.* Galilæus thinks that he invented a new Science concerning Motion, *by supposing that heavy Things are naturally carried towards the Center of the Earth with a Motion uniformly accelerated, i. e.* with such a Motion, that as it recedes from Rest, it continually superadds to itself equal Moments of Celerity in equal Times. But if it be false (as I think it not always true concerning many Causes) that there is such a Motion in the present Œconomy of Nature; yet because such a Motion may exist at the Pleasure of God, as implying nothing in it contrary to Possibility, therefore the Conclusions, which result by a lawful Inference from such a Supposition, ought to be accounted for lawful Demonstrations. In like manner though what is supposed in Mechanics, *viz. that every Point of heavy Bodies do press, endeavour, or incline to Motion along Right Lines parallel to one another*

other and perpendicular to the Horizon, and consequently that equal Weights do equiponderate at equal Distances; I say, though this be really contrary to Nature, and in that respect false; yet because it may be clearly conceived, that all Bodies may have such Propensions, the Conclusion therefore, which is built upon such an Hypothesis, ought to have the Dignity and Title of a *Demonstrative Theorem*. And the same Way, though what *Ptolemy*, *Copernicus*, and all other Astronomers advance, viz. *That the Motion of the Stars is in perfect Circles or Ellipses, and that they are every Way regular and equable; also that they keep the same Periods of the Times, and the same Orbits, with a perpetual Constancy,* and other such Things of this variable and uncertain Nature; I say, though I imagine all these to be false, at least unknown in respect of those Stars; yet because nothing hinders, but God may create such a World, where the Stars will exactly agree with such Motions; therefore the Demonstrations depending upon such Hypotheses are most true, and their Astronomy true, not indeed of this World, but of the other, which is supposed capable of being created by God. For God has given us the Power of creating innumerable imaginary Worlds in our Thoughts, which himself, if he please, can cause to be real. Lastly, though no such Notions be ever found in the Nature of Things, as Geometricians suppose to be described by *Spiral Lines, Quadratrices, Conchoids, Cissoids, &c.* notwithstanding since nothing hinders, but there may be such, as well as many others not unlike, which we daily Experience, therefore the Conclusions, which follow from such Suppositions, are rightly demonstrated. For the Dominions of Reason do far exceed the Limits of Nature; the intelligible World is vastly farther extended and more diffusive than the sensible World,

World, and the Understanding contemplates many more Things than the Sense.

Every particular Science of this Kind produces its own Hypotheses, which require no other Proof, but to be explained and demonstrated by some Example or Experiment more intelligible, and suitable to the Capacity of the Learner, and their Possibility made evident as far as it may be done; to which if he obstinately refuse to acquiesce, nothing remains but to give up all Thoughts of any farther proceeding, and the Way-ward Person be left to his own Liberty, as an unfit Learner of the Science proposed. *Ex. gr.* If any one deny that the *plane Figure* (which is called a *Circle*) may be produced by the *Rotation of a Right Line*, and will not be convinced, that any such Thing can be done or conceived (by the obvious Use of a Pair of Compasses, or the Revolution of a Wheel above its Center), he is to be admonished to apply himself to some other Study, and no more concern himself with Geometry.

Moreover it will also appear hence, what and what Sort of Truth that Kind of *Principle* obtains, which is wont to be called a Definition; *viz. that it is a Proposition shewing the Name of something that results from some possible Supposition.* As for Example, (for I always study to illustrate Matters with the most easy and familiar Examples) if we suppose three Right Lines so to meet in some Plane, as to include Space, or constitute a certain Figure, I call that included Space or constituted Figure a *Triangle*; whence we have the following Definition of a Triangle, *A Triangle is a plane Figure comprehended by the Concurrence of three Right Lines.* If we suppose a Semicircle to be revolved about its Basis or Diameter which is at rest, till it be restored to its first Situation, I stile the Body produced by that Rotation a *Sphere*; whence the Definition

nition of a *Sphere* will be, a *Body generated from one compleat Revolution of a Semicircle about its Diameter.* Lastly, If we suppose the Earth to be placed between the Sun and Moon, from which Position the Light of the Sun is intercepted, and the Obscuration of the Moon, which is called an *Eclipse*, results; hence the Definition of an *Eclipse* is, *an Obscuration or Privation of Light in the Moon by Reason of the Interposition of the Earth.* Hence we perceive that the Truth of a Definition is merely arbitrary as to its Subject. For that is no more than a mere Name imposed contingently, and at pleasure; being either feigned by the Teacher of the Science of his own Authority, or taken from common Use, or approved by the Consent of the Learned; and no where signifies the Thing defined from its own Nature, but altogether from the Institution of Men: Wherefore that Name can no otherwise be demonstrated to agree with the Predicate, than by appealing to the Authority of Lexicons, to vulgar Use, to the Suffrages of the Learned, or at least by arrogating to one's self that Right, which belongs to any Teacher. But as to the Predicate, it appears that the Truth of any Definition depends upon the Possibility of the Hypothesis which it includes, so that to make a Definition true, the Name assigned must belong to a Thing following some possible Supposition expressed in it. From whence moreover it appears, that Definitions of their own Nature are no otherwise demonstrable, than the Hypotheses themselves are, from which they proceed; *i. e.* than by shewing that the Name is adapted to a Thing having a manifestly possible Condition in Nature, according to what is inculcated above. For properly speaking, that which is impossible and inconsistent has neither Definition nor Affection. We may understand with *Aristotle*, what is signified by the Word

Hircocervus, but it cannot be defined; because such a Thing cannot exist. As to the Truth of all other Axioms, it is derived, as was just now insinuated, from the Presupposition of the antecedent Definitions, by a lawful Argumentation. As *ex. gr.* these Axioms which occur in the Elements: *All Right Angles are equal. Right Lines include no Space: All Right Lines drawn from the Center of a Circle to its Circumference are equal*; these, I say, may easily be inferred from the just Definitions of a Right Angle, Equality, included Space, and a Circle; but ought to be inferred so, as to preserve the Dignity of Axioms. And I doubt not but, after the same manner, Things, which seem most clear of themselves, and do most readily command the Assent of every Hearer, may with the utmost Quickness be gathered from Definitions. And because the Suppositions from whence these Definitions do result, as above, are of all Things the most evidently possible, as being daily agreeable to innumerable obvious Experiments, and most simple in their own Nature, so as not to escape the Observation, or exceed the Capacity of any one; but do moreover follow these Axioms, not after long Circumstances but immediately; hence the Discursus by which they are proved becomes imperceptible, or altogether none at all, as it usually happens; those Things which are most easily done, are not perceived how they are done. Just as it happens with an accomplished and skilful Musician, who scarce seems to himself to touch the Instrument so much by Art, as Instinct, hardly perceiving the Motion of his own Reason, or the Exercise of his Memory. For because we daily see various Magnitudes in part to agree with one another, as to all the Sorts of Dimensions applied to them, *viz.* to fill the same Space, or be extended between the same Bounds; we therefore easily
grant

grant such to be supposed: And also since it is confirmed by Use, that the Habitude or Relation of Magnitudes one with another, which results from this Supposition, is called Equality; we thence easily either deduce of ourselves, or grant to others affirming it (by Reason of our speedy Apprehension of the Possibility of the Hypothesis, and the Agreement of the Definition), that whatsoever Magnitudes are equal to the same Magnitude, are also equal to one another. Therefore even the most plain Axioms do scarce any otherwise differ from other Theorems, but as they approach nearer to the first and most simple Hypotheses and Definitions, and consequently are more briefly and easily demonstrated.

From what has been said, may be known the Original of all Natural Science, and the genuine Method of reasoning even from the first Fountains of Knowledge; which is nearly thus. The Mind, from the Observation of the Things objected, takes Occasion of framing like Ideas, which, as soon as it clearly perceives to agree with the Things that may exist, it affirms and supposes; then appropriating Words to them forms Definitions, and from the Consideration and Comparison of these together it draws Consequences and makes Theorems, which being joined together into certain Systems do compose particular Sciences.

From whence again it seems to follow, that there is no need, at least in Speculative Sciences, for supposing any *physical Anticipations, common Notions, or congenite Ideas*; since the Mind may be sufficiently instructed without them, and by its Native Power acquire to itself the necessary Principles and Means of Science, as has been shewn. The Thing indeed is different with Regard to practical, by which I chiefly mean moral, Sciences: For the Principles of these do not so much

seem to be gathered by Discourse, as to flow from Appetite or natural Instinct. *Ex. gr.* Such Principles of moral Science as these; *Whatsoever is agreeable to Nature, pleasant, and profitable, is to be loved, embraced and pursued: Every Thing hurtful to Nature, unpleasant, and unprofitable, or which brings Loss, Grief, or Destruction along with it, is to be abominated and avoided.* I say, such Axioms do not seem to depend upon, or be derived from, any Argumentation, but to be known the same Way as we see, that bitter Tastes, stinking Smells, frightful Spectacles, and other Things ungrateful to Sense are avoided, even by Brutes themselves, and the contrary Things embraced by them. Therefore we affirm nothing concerning such Sciences, but confine ourselves to speculative Sciences. Nor do I very stiffly deny, that there are at all such common Notions in these; but I am hence inclined to think, that they are not supposed necessarily, much less, that there is any need to invent, or devise any *Platonic Remembrances*, and I do not know what Resuscitations of the Mind as asleep.

Moreover it seems no less to appear hence, that the Truth of Principles does not solely depend on *Induction*, or a perpetual Observation of Particulars, as *Aristotle* seems to have thought; since only one Experiment will suffice (provided it be sufficiently clear and indubitable) to establish a true Hypothesis, to form a true Definition; and consequently to constitute true Principles. I own the Perfection of Sense is in some Measure required to establish the Truth of Hypotheses, but the Universality or Frequency of Observation is not so.

I might here adjoin many Things, but these may suffice to be spoken in general, concerning the Nature of Principles. And indeed I have prolonged my Discourse upon these Things longer than

than I thought, and perhaps than I ought, or will be acceptable to you; the Meditation insensibly drawing me on. Yet I hope not altogether unprofitably, since it is in the highest Degree expedient for such as study the *Demonstrative Sciences* to have a thorough Knowledge of the Nature of Demonstration itself. Wherefore I hope you will pardon this Freedom, and take what I have said in good Part, as proceeding only from an attentive Consideration of the Thing, and examine it freely and diligently.

I now apply myself to distinguish the Species of *Principles*, *i. e.* to enquire how many different Sorts of *Principles* there are: Which Controversy though it may be easily decided from what has been already said, yet I think it worth the while to relate the Thoughts of others, that ye may be better able to judge what is most agreeable to Reason, after a due Consideration of the Opinions of all. But I am not willing to provoke your Patience farther at the first Onset, wherefore I will refer this Disquisition, with some other Things concerning *Principles*, perhaps not unworthy your Observation, unto the next Lecture.

LECTURE VIII.

Of the Division of First Principles.

I HAVE very lately made some general Observations concerning the *Nature, Condition, Origin* and *Truth* of *Principles*. It remains that we enquire what Authors deliver and what Reason dictates concerning the Number of their different Species.

Since *Aristotle* seems a little obscure, and almost inconsistent with himself, in this Matter ; we must not entirely follow his Opinion, yet we will endeavour to find it out by comparing different Places, and examine it when found. In the *Second Chapter* of the *first Book* of the latter Part of his *Analytiks*, he makes three Kinds of *Syllogistical Principles*, viz. *Axioms*, *Hypotheses* and *Definitions*. For first he distinguishes them into *Axioms* and *Positions* ; and then subdivides *Positions* into *Hypotheses* and *Definitions*. The Nature of an *Axiom* he thus explains, *that it is such a Syllogistical Principle, as cannot* (or as ought not to) *be demonstrated, and the Learner ought to have* (i. e. understand or admit) *it necessarily*. And an *Hypothesis* and *Definition*, as they are comprehended under the more general Name of *Position*, he defines conjunctly to be *such a Principle of Demonstration as likewise cannot* (or ought not to) *be demonstrated, and is not understood by the Learner of Necessity*. Then these, as they are distinguished from one another he defines thus. *An Hypothesis is a Position which takes Something to be or not be ; as that there is Magnitude, that Unity is granted*. A *Definition* he pronounces to be *a Position which assumes that Something is : as that Unity is an undivided Quotity* (or *Quantity*). But in the tenth Chapter of the same Tract, he seems to assign three other Kinds of *Principles*, viz. *Common Axioms*, *Hypotheses* and *Postulates*. And he thus distinguishes *Hypotheses* from *Postulates* : *When* (says he) *he who demonstrates assumes without Proof whatsoever may be demonstrated, and if they are agreeable to the Learner, supposes them, neither is this simply an Hypothesis but in respect of him alone ; but if the Learner have no, or even a contrary Opinion of these Things, then is such an assuming of them a Postulate*. And an *Hypothesis* and *Postulate* differ in this. For a *Postulate* is
that

that which is besides, or contrary to the Notion of the Learner ; or which, when it is demonstrable, is received and applied without Demonstration. So that from the Comparison of these Places, there seem to be five Sorts of Principles, according to Aristotle, viz. Axioms, Indemonstrable Suppositions, Definitions, demonstrable Suppositions, and Postulates. But those before are contrary in Specie to these deliver'd here. For there he seems to deliver Principles absolutely indemonstrable, a Position being defined that which is not to be demonstrated ; but here he expressly declares the Hypotheses and Postulates assumed to be demonstrable. For reconciling which Things, it may be said, that in the former Place the Philosopher respects the first Principles of every Science simply, which certainly should not be demonstrated, since thus they would not be the first ; but in the latter, he points at the particular Principles of the subjected Sciences, which nothing hinders but they may be demonstrated (as has been shewn above ;) or at least, he means that no Principles may, or ought to require, or admit of Proof in that Science, where they are used as such, tho' in others they may.

But something I dislike in this Aristotelian Account of Principles and their Explication, which I speak with all due Regard to the Honour of that great Man, for whom, notwithstanding, I preserve the greatest Veneration and Esteem, by reason of his most profound Wisdom and extensive Learning, and would have all Men to do the same. His Trichotomy indeed into Hypotheses, Definitions, and Axioms, as to what belongs to the Members of the Division in general, and with Respect to every Science, seems to be most perfect ; but as to the Explication otherwise. For he shews in his Examples, that he understands nothing else by an

Hypothesis than the *Position* or *Affertion* of the Existence of the Subject concerning which it is treated in any Science or Demonstration. As, (*f*) *That Unity may be given. That Magnitude may exist. It must be taken for granted, (says he) that both Unity and Magnitude do exist, but the Existence of the rest is demonstrated.* But such an Hypothesis seems to be altogether unfit for Science, since nothing can be inferred from it, nor is it wont to enter any Syllogism. For pray what Conclusion can follow or be derived from hence *that Magnitude may be, or may be given; that it may or can exist?* None indeed that I can find. But from hence *that it is such, that it is endowed with such a Property, that it may obtain such a Situation and such a Motion,* it may follow, from the admitting and comparing of some Properties, that it obtains others along with them. Therefore the aforesaid Supposition is not rightly taken for a *Principle* of Demonstration. For it belongs to such a *Principle* that it be fit to beget something, as a Conclusion from itself, and serve for the Proof of others. But from the bare Position of a Subject, *That it is,* nothing else can follow but *That it is, viz. It is, therefore it is.* I own indeed, that antecedently some Knowledge or Conception of a Subject is presupposed to the Science of all Things, as far as every Proposition is gathered from incomplex Terms, which can be no otherwise apprehended than as significative of Things having some Kind of Essence, *i. e.* by conceiving or supposing that they are; but incomplex Terms, implying Essence, are not therefore the Principles of Demonstrations, but rather the Matter or Integral Parts of them.

I do also very much disapprove of that Assertion of Aristotle, *that a Definition affirms nothing,*

(*f*) I. Post. 10. 8.

or receives neither Part of a Contradiction ; i. e., he takes a *Definition* not for an entire Proposition, but only for its *Predicate* ; as *ex. gr.* that he is a *rational Animal* is the *Definition* of a Man, and for that Reason a *Principle* of *Demonstration* ; but not this Proposition, *A Man is a rational Animal.* But how agreeable is this with his own *Definition* of a *Principle*, viz. that it is an *immediate Proposition* ; and how conformable to the Nature and Quality of a *Principle*, which requires that it be a *Truth*, and such a *Truth* as may have other *Truths* deduced from it ? For since *Truth* is the Quality of a perfect Proposition, and not of a simple Term, therefore nothing can be drawn from the Apprehension of the latter. Why, according to him, is a *Definition* named a certain *Position*, if nothing be put or affirmed ? How, lastly, can it but be very absurd, thus to take a *Definition* with *Axioms*, which are perfect Propositions, and with *Hypotheses* which, according to himself, do affirm something, are compared, conjoined, and agree together the same way as *Principles* ? The *Definition*, which is accounted a *Principle* of *Demonstration*, is really a compleat Proposition predicating concerning the proposed Subject some Affection of itself, which is useful for inferring other Affections. I say it is a certain special Proposition of a demonstrative Syllogism, shewing the Cause of the Property demonstrated, as far as it may be done. Indeed an incomplex Definition, or the Predicate of a complex one, may be, and most frequently is, the Mean, or Argument found and made choice of, for raising a *Demonstration* ; but it is not therefore a *Principle*, no more than a *Whole* and a *Part* are therefore *Principles* of *Demonstration*, because that *Axiom*, *The Whole is greater than its Part*, is reckoned among *Principles*. I say nothing that *Aristotle's* Affirmation is

not

not always true, *that Axioms cannot be demonstrated*, because his Words, as was hinted above, do admit of some Excuse, and an useful Proposition. But of the other two kinds of Principles he subjoins *viz. Hypotheses* and *Postulates*, which, tho' otherwise demonstrable, are assumed by the Demonstrator as granted, these I imagine differ nothing at all from *Axioms*. For whatsoever may be demonstrated is a *Theorem*; but a *Theorem* which is not proved in any particular Science, but is taken from some superior one, obtains the Place of an *Axiom* in that particular Science.

But I see very little Foundation for *Aristotle's* Distinction between an *Hypothesis* and *Postulate*, that a Learner should willingly subscribe to that, but dissent from this. For howsoever it be concerning the preconceived Opinions of a Learner, which matter nothing, whether they agree or disagree with the Mind of the Teacher; yet before the Learner comes to an efficacious Demonstration, it is necessary for him to give his Assent to certain Principles proposed, otherwise he will perceive no Science to have been inbred with him. It may happen, that the Learner may have Prejudices, but what is this to the Purpose of the Science? If he have any, he must throw them off, or lay them aside; and be convinced by the Master's Arguments, or instructed by clear Examples of the Matter proposed, before he can obtain a perfect, absolute, and properly called Science. For pray what Energy will there be of a Demonstration, what Effect, if the Learner can't assent, can't acquiesce, nay can't firmly adhere to the Premises? Nor will I say how justly that can be called a *Postulate*, which may be demonstrated. For why is that taken precariously, which may be assumed of right, and wrested by Violence? Or why does not the Learner oppose the idle Persuasions

sions of the Master? So that I can't see what led the Philosopher to this Distinction, nor does his Interpreters remove the Scruple.

As to what is said by *Proclus* (for first of all I aim at him) while he professes to follow *Aristotle*, he, in my opinion, renders all things worse. For 1st. He attributes three kinds of Principles to *Euclid*, viz. *Axioms*, *Hypotheses*, and *Postulates*, whose Differences he expounds according to the Sentiment of *Aristotle*: But as if *Definitions* were not Principles, nor did either *Euclid* or *Aristotle* ever account them for Principles, nor did the latter most expressly distinguish them from *Hypotheses*. Therefore the Blindness of *Proclus* seems wonderful, both in wholly omitting *Definitions* in his Enumeration of Principles, and in confounding them with the *Hypotheses* of *Aristotle*; while he very incongruously attributes those Things to the *Definitions* and *Postulates* of *Euclid*, which *Aristotle* ascribes to his demonstrable *Hypotheses* and *Postulates*. For how are *Euclid's* Definitions and Geometrical Postulates demonstrable? How is it necessary for the Sentiment of a Learner to be opposite to the Postulates of *Euclid*? Or how can that be truly adapted to them, that however a Learner refuse his Assent, yet he is admitted a Hearer whether he will or no? What is this else but to overturn the Foundation of Geometry, and destroy all Learning at once? Whereas the Postulates of *Euclid* do carry so clear a Possibility, and may be illustrated with so many familiar Examples, that no Genius capable of Science can any way impugn, or find Fault with them: Nay, otherwise a Teacher would become immodest, importunate and trifling, who should require or suppose it; and in vain would go about to teach or demonstrate, his Postulates being not admitted. But why do I oppose *Proclus*, when he opposes himself, and seems to remove those

those undigested Notions in the beginning of his third Book, which he had inserted from *Aristotle* in his second. *It is always necessary*, says he, *that the Principles of these be indemonstrable and self-evident*, at the same Time adjoining many other Things to the same Purpose clearly repugnant to what was before advanced, and to *Aristotle's* Description of Postulates, which he seems to espouse.

But dismissing *Proclus*, let us see what *Ramus* says to these Things: He blames *Proclus*; but how? Why so, as entirely to take away all Difference of Principles, indeed with a singular Moroseness. But upon what Arguments? *Because*, says he, *Definitions, Divisions, and all other self-evident Propositions are admitted into Disciplines, not in the name of a Postulate, or an Axiom, but only of their own Clearness and Perspicuity.* Which contain almost as many Paralogisms as Words. For who ever believed *Definitions* to be admitted into any Discipline under the Title of a *Postulate*, or an *Axiom*? Who that treated accurately of any Science did not separate *Definitions* from *Axioms*? And tho' no Body had distinguished them, could they not therefore be distinguished? Whence then are there so many little Distinctions of them? But, says he, they are admitted only *in the Name of their Clearness, i. e.* I suppose, not as they are *Definitions* or *Axioms*, but because they are *clear*: Be it so, what follows? Therefore he concludes, they ought not to be distinguished: A fine Consequence indeed, and very like the following one. The Sun and a Candle are beheld not in the Name of the Sun and a Candle, but because they shine clearly; therefore the Sun and a Candle ought not to be distinguished; or therefore the Light of the Sun and of a Candle are the same. But he argues moreover, That this Difference of *Principles*

ples is only used by *Euclid* in his first Book, in the following Books it is contemned: Contemned is it, how does that appear? Certainly he elsewhere uses other *Definitions* and other *Axioms* as occasion requires; it is true he adds no more *Postulates*, because there seems to be no need of more: But where does he confound those Species of *Principles*, or declare his Contempt of any of them? Unless not unseasonably to name them be to contemn them.

But perhaps he will object the most weighty Authority of *Archimedes*, who promiscuously calls the Principles laid down before his *Isorrhopic Postulates*, or Things required. *We require it as a Postulate*, says he, *that equal Weights hanging by equal Lengths do weigh equally, or are in Æquilibrio.* And after the same manner does *Euclid* in his *Optics* call all the *Principles* he assumes *Hypotheses*: *Geminus* with *Proclus*, and *Eutocius* did once make the same Observation concerning *Archimedes*: To which Instance I answer, that perhaps *Archimedes* studying Brevity, and not willing to make too great an Apparatus to a small Book, did on purpose neglect that extreme Exactness, which he observed in his *Books of the Sphere and Cylinder, of Spiral Lines*, and other more curious Pieces, where he separates Definitions from Axioms. Nor is it any wonder for the same Words to be sometimes more, and sometimes less extensive, according to the Design and Purpose of the Writer. Like as the *Stoics*, those famous Reformers of Things, as well as Words, do give universal Propositions the Title of *Axioms*, as if they meant to make all Propositions equal in Dignity, as they have done of Virtues and Vices. Nor do I deny but the word *Postulate*, or *Petition*, from its vulgar Signification, may be fitly enough attributed to all kinds of Principles. For a Teacher must in Part *peti-*
tion

tion, because he must by all means procure the Assent of the Learner. And this surely is more modest than to be said *to command*, as the Masters of Disciplines do often call their Dictates *Precepts*, i. e. *Commands*.

Rivaldus argues not ill upon this Place of *Archimedes*, *We may petition* (says he) *that this or that be so named; then that this or that be taken as established, which we know by the Light of Nature; lastly, that this or that is possible to be done. But every thing that can be done, or so named, we cannot term an Axiom, nor will it be allowed that the Knowledge which is innate to our Minds is a Definition.* Which is apposite enough. I adjoin *Proclus*: Some now, says he, think it proper to call all Principles *Petitions* as they do all things sought *Problems*. *Archimedes* therefore who studied Brevity, and was willing to comprehend his Principles together in one Body might not unfitly assign to them the name of *Petitions*, because he could not equally adapt the Title of *Definitions* or *Axioms* to them all. And by the same Authority might *Euclid* and others call their Principles *Hypotheses*. For that Word also is capable of a most extensive Acceptation: Nor can any Thing, which is useful to go before a Demonstration, be improperly called an *Hypothesis*, i. e. a *Supposition*, or as it were, a Foundation laid, upon which the following Demonstrations are to be superstructed. *Archimedes* is wont to speak thus: *ex. gr.* Before his *Books of the Sphere and Cylinder* after his *Definitions and Axioms*; *These things*, says he, *being laid as a Foundation*: Before the *Definitions* premised to his Book concerning *Conoids and Spheroids*: *These are laid as a Foundation*: In his Book concerning *Spirals*; *The Things* (says he) *of Use for their Demonstration are laid down before*; where the Words rendered *laid as a Foundation*,
and

and laid down before, are evidently of the same signification in the Original. To suppose then univerfally fignifies to premise, or to lay down as a Foundation; in which Sense it agrees with all Principles. So also to assume, or take for granted, tho' it be more properly accommodated to Axioms: As in his Books concerning the *Sphere* and *Cylinder*, where *Archimedes* being about to lay down *Axioms* after the *Definitions* he had delivered, fays, *These I assume.*

I must not pass over that new Genus, or at least new Name of Principles, which the just now mentioned (g) Commentator of *Archimedes* has hence coined for us, called a *Subsidy* or *Reserve*. *Archimedes* had spoke of other Premises to his Demonstrations, after his Definitions. Therefore, fays he (b), after we have writ of Theorems and the *Epitigmata* which are useful to their Demonstrations, we will next proceed to write to you of Problems. Hence *Rivaltus*, interpreting *Epitigmata* Subsidies or Reserves, imposes the Name of *Subsidies* to certain Definitions, which in my Opinion are misplaced. But *Archimedes* by *Epitigmata* seems to understand nothing else but certain subsidiary Propositions or *Lemmata* made use of in the Course of the following Book, which were requisite to the Demonstration of its primary Theorems; therefore the *Epitigmata* which follow, or are inserted in their Order, are to it like those *Coborts*, which the Writers of the *Roman* History are wont to call *Epitigmata* or *subsidiary Coborts*. Tho' I very much suspect that *Archimedes* used no such Words, but perhaps *Ἐπιτάγματα* has crept in by the Heedlessness of the Transcribers for *ἔπι ταῦτα*; so that instead of the *Epitigmata* which are useful to their Demonstrations, as above, it should have

(g) *Rivaltus.*

(b) In libr. de Conoid. & Spheroid.

been, *the other Things which are useful to their Demonstrations.* Tho' I deny not but the Name *Epitagma* or *Subsidy* is here apposite enough, and is somewhere to be found in *Pappus*; yet so that we can scarce know from the Context in what Sense it ought to be taken. But I am afraid these Fightings with Shadows, these Trifles, these worthless Distinctions give you little Delight: To me indeed it is grievous that while hunting after Accuracy I find myself fallen into Loquacity.

That therefore I may the more speedily rid myself of this Question, passing by the Opinions of others about the Matter, I thus briefly and conformantly apply to what has been said.

The Kinds of *Principles* simply so called, *i. e.* such as are indemonstrable, which cannot, or ought not to be demonstrated, are two, *viz.* *Hypotheses* or *Postulates*, and *Definitions*.

Hypotheses are Propositions assuming or affirming some evidently possible Mode, Action, or Motion of a Thing, *ex. gr.* *Suppose a Point to be carried with a direct Motion from the Place A to the Place B: or let it be granted that a Point may be so carried.* *Suppose a Right Line be carried about, with one of its Extremes fixed or immoveable, 'till it be turned to its first Situation: Or let it be taken for granted that a Right Line may be so turned.* *Suppose two Right Lines to meet, or intersect one another, so as to go different ways after their meeting.* *Or let it be granted that two Right Lines may so meet.* *Suppose a right-angled Triangle to be revolved completely about one Leg of the Right Angle.* *Suppose the Right Line AB (FIG. IV.) with the extrem A to be turned about uniformly (i. e. so as as make equal Angles in equal Times) and the Point A in the same Time to be carried uniformly along the Right Line AB, i. e. so as to make equal Intervals in equal Times.* *Suppose a Point to go about in the Circumference*

cumference of a Circle or Ellipsis so as to make equal Angles in equal Times, in respect of a Point assigned, which let be the Center of the Circle, or Focus of the Ellipsis. Suppose a Right Line to be extended from some Point of a lucid or enlightened Body to the Eye. Suppose the Moon to be placed in a Right Line between the Sun and the Eye. Suppose a Ray to be derived from a visible Point through the Center of the Eye, or to the Center of the Tunica Retina. Of such Positions the Sense it self proves, and Experience clearly attests that they are not rashly assumed, but ought to be admitted, *i. e.* that they contain nothing repugnant to Possibility. From whence it appears by the Way, that as there is a very near Affinity between *Axioms* and *Theorems*, which was observed by the Ancients, so there is the same between *Hypotheses* and *Problems*. For as a *Problem* shews the Manner, and demonstrates the Possibility of some Structure; so an *Hypothesis* assumes some Construction which is manifestly possible. To which Purpose *Proclus* speaks well according to the Sentiment of *Geminus*. *In a Postulate or an Hypothesis, says he, as in a Problem, what is easy to be done is assumed; in an Axiom, as in a Theorem, what is easily known is granted.*

A *Definition* is a Proposition wherein a Name is imposed or ascribed from some possible Supposition of a Thing clearly resulting; which Supposition, being expressed in the Proposition, determines and circumscribes that Name. As, insisting on the above mentioned Hypothesis, *What results from the Meeting of two Right Lines intersecting on one another may be called a rectilinear Angle: Or a rectilinear Angle is that which is made from such a meeting. The plane Figure which is produced from the Rotation of a Right Line may be called a Circle: Or a Circle is a plane Figure which is produced by the Circumduction of a Right Line. The Solid which pro-*

ceeds from the Revolution of a rectangular Triangle about one Leg of the Right Angle may be named a Right Cone: Or a Right Cone is a Body generated by such a Revolution. The Curve Line which is made from two uniform Motions, viz. Right and Circular, may be called a Spiral: Or a Spiral is a Curve Line engendered by such a Composition of Motions. The Motion in the Periphery of a Circle or Ellipsis making equal Angles in respect of an assigned Point may be called a Mean Motion: Or a Mean Motion is that which is so affected. The Right Line extended from any Point of a lucid or enlightened Body towards the Eye may be named a Ray. The Privation of the apparent Light by the Interposition of the Moon may be called an Eclipse of the Sun. The Ray flowing from a visible Point thro' the Center of the Retina, may be called the Optical Axis. From which Examples the Nature and Origin of a Definition abundantly appears; that in it the Name reciprocally agrees with the Thing, and the Thing with the Name: Or that the Signification of this is adequate to the possible Existence of that.

From these two emerges a third Kind of Principle by a Syllogistical Consequence, which is wont to be called an *Axiom*, *Dignity*, *Pronunciatum*, *Common Notion*, or *Anticipation*. But this is nothing but a certain Theorem in some superior precedent Science, which is clearly deduced and demonstrated from the proper *Definitions* and *Hypotheses* of that Science either immediately, or by other intermediate Theorems; and consequently is assumed without Proof in the subordinate Science, or at least emerges from some *Hypothesis* or *Definition* belonging to that Science by a most easy and evident Consequence, in the form of a *Confectary*. Which Species of *Axiom* is wont to be called *proper* to that peculiar Science, as the other

is called *common*, as being *common* to all the Sciences subjected to the said *primary Science*. *Ex. gr.* *That those Things which are equal to the same, are equal to another*, is accounted a *common Axiom*, because it agrees with Numbers, Times, Motions and Weights, as well as Magnitudes; and is only demonstrated in Metaphysics, as having there the Reason of a Conclusion, or Theorem: But *That all Right Angles are equal*; or *That two Right Lines include no Space*, these are *proper Axioms*, obtaining the first Place in Geometry only, as being inferred and after a Sort demonstrated from the Definitions of a Right Angle and a Right Line. But these Things we have already sufficiently expounded in the Examples above.

Thus we have come at last exactly to *Aristotle's* first Division in the Second Chapter of the first Book of the former Part of his Analytics, *viz.* into *Hypotheses*, *Definitions* and *Axioms*; though we disapprove his unaccurate, at least obscure Explanation of them. We have also come up to our *Element-Composer*, who in like manner distributes *Principles* into three Classes, *viz.* *Definitions*, *Postulates*, and *Pronunciata*. For it is all one whether indemonstrable Suppositions be called *Hypotheses* or *Postulates*; only they are not thought to be therefore called *Postulates*, because the Demonstrator assumes them precariously, and as it were begs them: For they have an irrefragable Certitude and Evidence, in no wise inferior to the Clearness of *Axioms*; nay seem more clear than many *Axioms*, because these depend and are derived from those. They may also put on the Form of *Axioms*, as *Problems* do that of *Theorems*, neither do they at all differ from those, except as to their Form, and because they cannot be demonstrated like those.

The Modesty of the Name ought by no Means to detract from the Excellence of the Thing.

But we may take Notice of something that may be objected against what has been said, *viz.* that two Propositions are reckoned by *Euclid* for *Postulates*, to which the Explication here brought of a *Postulate* or *Hypothesis* does not agree, *viz.* these; *That all Right Angles are equal to one another; And if a Right Line insisting upon two other Right Lines do make the internal Angles at the same Parts of the insisting Line lesser than two Right Angles, that those two Right Lines produced towards these Parts do at length meet.* I answer, this is unaccurately done by *Euclid*, (if it be done by him, and these Propositions have not crept into a Place not belonging to them, by the Fault of others) and therefore they are more rightly reckoned *Axioms* by *Geminus*, *Proclus*, and most other Interpreters. For they are really Theorems consequent to the Definitions of a Right Angle and a Parallel Line.

After I had thought of these Things concerning *Principles* and their Division, by chance casting my Eyes upon that elegant and useful Book of *Alphonfus Borellus*, containing the Elements of Geometry digested in a New Method, which he calls by the Name of *Euclid restored*, I found he had there bestowed the greatest Care and Subtilty in illustrating the *Nature* and *Distinction* of *Principles*, and that both in the Proem of the Work, and especially in those that immediately go before the first Proposition of the *Elements*. Perhaps I should have observed something among some of his Dictates, if they had offered themselves before; but since they contain scarce any thing different from our own Thoughts, from what I myself have thoroughly handled heretofore; and since we have already discoursed more than enough
upon

upon this Matter, for the present, I will pass them by untouched : yet afterward, when Opportunity permits, I will perhaps examine one or two Points, and especially those which the Opinion of *Clavius* concerning the Nature of Definitions seems to contradict. In the mean Time I betake myself to certain particular Things to be observed concerning *Postulates* or *Hypotheses*, *Definitions* and *Axioms*.

As to *Hypotheses*, both their Foundation and Reason, their Matter and Extension, may be observed in general. The Foundation and Reason of *Hypotheses* (as we have often intimated, for we cannot, if we would, avoid oftentimes repeating the same Thing, which is not indeed altogether amiss, but partly useful in such Lectures as these ; since the Sense of the Words, and the Meaning of the Speaker, are by this Means more clearly perceived and deeply rooted), the Foundation, I say, of *Hypotheses* is evident from Experience, or through some Sense whereby we apprehend Things offered from without ; or lastly, through the secret Consciousness, whereby we perceive internal Motions, and the Actions remaining within us. For nothing ought to be supposed, whereof we can make no Experiment, nor can illustrate or confirm it by some apposite Example : since the Possibility of an *Hypothesis* can be shewn no otherwise ; of which notwithstanding the Student must have a certain Science. That *Hypothesis* *ex. gr.* in Optics, *That a Ray or luminous Right Line may be extended from any (at least a Physical) Point of a visible Object to the Eye wheresoever placed in a homogeneous Medium ;* this, I say, would by no means be admitted, if it could not be supported by this notorious Experiment, that an Object is every where seen, except there be by a Body placed somewhere in a Right Line between it and the Eye. Nay it would seem incredible and almost impossible (by

reason of the Unintelligibleness of the Manner of its Performance, and the imperceptible Subtily of its Nature), if Experience did not plainly confirm us in the Truth of it. So if any Thing less probable, or less examined, be delivered to a Student, in the Room of an Hypothesis, the Master of the Science is bound to shew it by a plain Example or Experiment, (or as (i) *Aristotle* says, by *Sense or the Finger*) so that before he proceed farther to Demonstration, there must remain no Hesitation concerning the Possibility or Truth of the Thing supposed.

And every Action, Motion, or Mode of Being that falls under Observation, or may be apprehended by Experience, is the Subject of *Hypotheses*. Especially the Subject of *Mathematical Hypotheses*, which we principally respect, is extended to all the Affections of Magnitude obvious to any Sense. So that to comprehend the Subject of *Mathematical Hypothesis* rightly, the general Affections, of which every Magnitude is capable, ought to be diligently weighed. Wherefore it will next be fit to treat of them.

Some are very solicitous to find some *primary Notion* and most *essential Property* of Magnitude, from whence all the rest do flow: Perhaps a Labour fruitless and without foundation; since it may be there is none (as indeed in my Judgment, there is none) to which such a *Prerogative of Nature*, such a *Primacy of Order* does really in so peculiar a Manner belong; but Magnitude has many Properties, which do all agree to it equally in a like Connection, and are linked with it in the closest Chain, being involved and united both into it and into one another. Wherefore being not solicitous concerning their Order, I will strictly

(i) *Post. II. 7.*

and

and largely endeavour to explain such *primary Affections* of Magnitude, as are most observable, and which supply Matter for Mathematical Hypotheses. But I perceive I have undertaken a Business worthy a larger Exposition than to be finished in a few Words, and which I had rather not begin at all than be obliged to leave abruptly; and since I remember I have so often had the Experience, how much easier a Pardon is obtained for a Fault in Brevity than in Prolixity, and how much better it is to abridge myself, than nauseate my Hearers, I will reserve these Things to the following Lectures.

MATHEMATICAL LECTURES.

LECTURE IX.

*Of the Termination, Extension, Composition,
and Divisibility of Magnitudes.*

I Am very sensible how nice and difficult a Business I undertake, in attempting to treat of the *common Affections and Properties of Magnitude*, which occur to Experience, and consequently afford matter for *Mathematical Hypothesis*, and therefore I cannot but speak something by Way of Preface and Premonition. For these are Things, which it is very difficult not to render more perplexed by explaining, not to obscure by illustrating; Things for the most Part of so subtle and abstract a Nature, that the Imagination scarce can comprehend them, scarce can assign to each their just Bounds, or separate one from another, and consequently do elude the most piercing Sagacity, and fly away and escape him who endeavours distinctly to catch at their vanishing Ideas: So that what St. *Augustine* is reported to have said of Time, may not undeservedly be applied to most of them. *If none seek of me what Time is, I know; If any ask me I don't know.* For what *ex. gr.* is *Extension*? What *Space*? What *Motion*?

tion? Every one, that speaks of these, imagines himself to be clearly understood, even by the most Vulgar; but if you examine their Breasts, you will find most of them linked in inextricable Snares, hesitating in their Thoughts, and entangled in their Speech. Nay, the most subtle Philosophers, after the most diligent Contemplation with the exactest Care imaginable, when they come to discourse of these Things can hardly speak consistently, either one with another, or the same with themselves: and seldom do any handle them so, but monstrous Paradoxes, and most grievous Difficulties, seem to follow.

Cartesius, ex. gr. from his Conception of Space infers the *infinite* or (to soften the Expression) *indefinite Extension* of Mundane Matter, with the *Impossibility of Vacuum*; and the *Immediate Contiguity of Bodies* which were at a Distance from one another before, by annihilating or removing all the intermediate Bodies; and such like Things as these: Which his Adversary *Hobbs* condemns and explodes (how justly I will not dispute), as contrary to common Sense. But does himself afford any Thing more clear and certain, or less incoherent and more blameless? Let us consider him a little: He terms *Space* the *Idea* or *Phantasm of Body*; *Place* the *Coincidence of Space with the Magnitude of a Body*; *Motion* the *leaving of one Place and acquiring another*. Now who does not see how repugnant these Things are with one another, and how very obnoxious to most ridiculous Consequences; to such *ex. gr.* as these: Therefore the *Place* of a *Body*, (*viz.* of this School) will be nothing else, but the *Coincidence* of my, your, or any ones *Phantasm* with the *Magnitude* of the School. As if the *Pope* of *Rome* did not reside in the *Vatican* Palace, nor live at *Rome*, but was placed every where in the *Fancies* of all
Men

Men that think of him : By which means he may easily be conceived an universal Pontiff. Therefore the Motion of a Stone or Arrow will be the leaving of one Coincidence of a *Phantasm* with a *Magnitude*, and acquiring with *Coincidence* : And while the *Turk* is marching an Army into *Hungary*, he is only wandering in your Fancy and encamping in your Brain. But pray does the *Magnitude* of a Body coincide or coexist with a *Phantasm* or *Idea* of the Mind ? How can the Coincidence of a Body with a *Phantasm* be lost or acquired ? How does a *Phantasm* separate and come between distant Bodies ? How can a *Phantasm* be occupied, be filled, divided, measured and subjected to so many other Attributes, which himself is not afraid to assign to Space, after he has delivered this imaginary Definition of it ? What if no Man, no Fancier should exist in the Universe, would there therefore be no other Thing ? Or would all Things necessarily be at Rest, but they could not be at Rest, since the *Phantasm* of Space does also belong to the Definition of Rest ? Could there, I say, be therefore no Space, no Place, no Motion in Being ? How mysterious, nay how absurd and contradictory are these Things ? These few Instances out of many I have produced by the by, to shew how hard, how difficult these *common Properties* of *Magnitude* are to be conceived and explained, since the most ingenious Men entangle themselves in Labyrinths, Difficulties and Inconveniences, while they are endeavouring to handle them with the greatest Accuracy. For which Reason I am the more pardonable, if I shall handle these Things, recite and explain them, perhaps after a meaner and poorer manner, more accommodate to common Sense than to metaphysical Conceptions ; and so far only as I judge useful to my Purpose, *i. e.* as they are subservient to *Mathematical Hypotheses*. But to come to the Purpose.

I. Of the Termination of Magnitude.

Of the principal and more common Affections of Magnitude the *first* that offers itself to us (for I confine myself to no Order, since as I took notice in the last Lecture, there is no Foundation of Order on the Part of the Thing between the *reciprocal* and *essential Properties* of the same Thing) I say, the *first* that occurs, while we are contemplating Magnitude, and presents itself to our Sense and Thought, is its *Termination*. Indeed we can approach nothing with Sense, but as it is terminated; we cannot penetrate the inward Parts of any Body, but only view its outward Film with the Eye, and touch it with the Hand. Neither can we conceive any Magnitude in Thought, at least distinctly, but only as it is contained and comprehended within some Limits. We may indeed have a confused Imagination of some Magnitude in Power, suppose a Right Line, as *Aristotle* said, infinite; *i. e.* produced or encreased at pleasure, or to a greater Distance than any Distance assigned, which consequently we denominate infinite. Nor is the Philosopher's Definition of Infinite improper, though very subtle; (*i*) *That is infinite, from which if one take any Quantity, something still may be assumed beyond.* But this is nothing else but to consider many Lines successively, according to a certain arbitrary and indeterminate Power, and not one real indeterminate Line distinctly; which according to the Philosopher again we cannot comprehend in the Mind. (*k*) *An infinite, says he, as such cannot be conceived or known.* The same is of an *infinite Subduction* or *Subdivision*, by which nothing else is understood, but that a Subtraction or Division may be continued at pleasure, without being brought to an Impossibility of proceed-

(*i*) *Phys.* III. 9. (*k*) *Phys.* I. 5.—II. 10.

ing farther. Again, (1) *Aristotle* speaking of Mathematicians says, *Mathematicians do neither want nor use infinite Magnitude, but take as much as they please, when they are minded to terminate it.*

When we conceive a *Line*, we form an Idea of something like a very fine Thread extended between two Extrems; or at least returning to itself with one Extreme, as is done in Curve Lines which include a Figure. When we think of a *Superfice*, we imagine something like an exceeding thin Cuticle or Plate encompassed with a very narrow Margin. When we Paint the Effigy of a *Body* with the Pencil of the Fancy, we for the most Part represent to ourselves a certain opaque Lump on every Side covered with an exquisitely fine and thin Veil. When we imagine an *Angle*, we conceive some intermediate Space included between two or more Lines or Superficies, or some such Thing. Nor is it otherwise concerning *Analogical Quantities*, viz. When we think of a *Weight*, we think of some Power capable of elevating some terminated Magnitude, *ex. gr.* one or more Pounds: When we meditate upon *Motion*, we imagine a successive Transition of some Body from this Term to that: When we reflect upon *Number* we imagine the Repetition of an Unit, beginning somewhere and ending somewhere, or of a Multitude bounded between two extreme Units taken inclusively. I speak almost according to the vulgar Notion; for in reality Units are not the Terms of Numbers, though themselves have their Terms, viz. the same with the Magnitudes they represent.

Therefore every Quantity is conceivable by us a different Way, being terminated in some manner, and as such, conduces not a little to Mathematical Hypotheses. For from hence especially we deduce the various particular Species or

(1) *Phys.* III. 11.

Dimensions of Magnitude ; and in some sort demonstrate. that they are not feigned at random, but have a real Existence after their own Manner. For we may argue thus : A *Body* or *solid Magnitude* (which no Person denies, as being palpable, and whatsoever can be presupposed farther) on no Part runs out to Infinity, but is terminated on every Side : Which *Term* or Boundary is not divisible inwardly, or *as to its Thickness* ; for if it should be so divisible, not the Whole, but only something of it without would be the Term, contrary to the Hypothesis. Hence there is given some *Term* of a *solid Magnitude* indivisible *as to Thickness*, which is called a *Superfice* : And so we have one Mathematical Hypothesis, and the Definition resulting from it. Moreover the said *Superfice* is not any where unlimited, but is included within some *Ambit* or *Extreme*, and that *Extreme*, by a like *Discursus* with the foregoing, is indivisible towards the inward Parts or *as to its Breadth* : Let the *Term* then of a *Superfice* be supposed indivisible *as to its Breadth*, which call a *Line* : So another Hypothesis and its connate Definition is had. In like manner this *Line* is not infinite, but inwardly, *i. e.* on either Hand it is included by a *Term as to its Length*, and by a like Reason are these *Terms* perfectly indivisible : let the *Term* then of a *Line* be supposed indivisible *as to its Length*, and call this a *Point* ; which is every Way indivisible, as partaking of the Indivisibility of a *Superfice* as to *Depth*, a *Line* as to *Breadth* ; and is immediately indivisible in respect of *Length* as being the *Term* of a *Line*. Hence a third Hypothesis with its conjunct Definition of a *Point*.

Whence it appears that *Points*, *Lines*, and *Superficies* are not devised by Mathematicians without Foundation. For though as *Terms* they seem scarce any thing else but Negations of farther

ther Extension ; yet as we have seen, they are Negations founded in the Thing, and well perceived by the Understanding, *viz.* like *Shadows* and *Darkness* in *Physics*, or *Improbability* and *Ignorance* in *Ethics* ; but if considered in another respect, they seem to be Attributes very real and positive. *Ex. gr.* It agrees, and is attributed to a Superfice, to be two Ways divisible, to be encreased, diminished, measured, be congruent, made equal, exceed, be deficient, also to be every Way moveable, and to rest. Nay, as I have intimated, *Superficies* only are immediately objected to the Senses, do subject the Rays of Light to Colours, refract and beat back the Undulations of Sound ; these do receive the first Impetus of Motions ; by these alone do Bodies mutually touch one another, seeing they cannot pervade or penetrate any Part of one another. Almost the same or the like Attributes belong to Lines ; by these are reckoned the Distances of Things ; according to these are directed the Rays of Light, the Descent of heavy Bodies, and all sorts of Motion ; by these are distinguished the Confines of Light and Shadow ; about these at rest are Bodies revolved ; and lastly, these are capable of being produced, contracted, divided, measured, and every way compared. Nor do Points themselves seem to want some kind of Reality, as having a somewhat obscure, and very subtle Entity. For these also do obtain Motion and Rest ; Motion indeed together with the Bodies in which they are, but Rest is often peculiar to them ; as *ex. gr.* to the Center of a Wheel, the Poles of the Earth or Heavens : for such Gyration is performed about something at Rest, and do preserve some Place of themselves immutable. Also the Moments of Bodies do consist about a Point, *viz.* the Center of Gravity ; in it they gather and unite their Powers ; are in some Sort supported

L and

and sustained by it; according to it their Motions obtain their Direction. Lastly, towards one middle Point in the Earth do all Things of their own accord, as with conspiring Wishes either incline and fall, or by a direct Passage fly back and recede from it. But let us hear *Proclus's* Elogium concerning a Point. (m) *The Centers*, says he, *in respect of Energy do sustain the Composition of the Spheres to which they belong, bounding their Distances, comprehending their Powers, and uniting them together into themselves: And the Axes, while themselves remain stably fixed, do turn, revolve, and carry them about them. And the Poles of Spheres, as determining the Axes, and of themselves comprehending all other Circumgyrations, do plainly denote that those Powers are not made up and compounded, but that themselves are the sole Commanders of the Union of those distant Things, and of the Cessation of the Motion. Whence Plato affirms them to be made of Adamant, a thing fixed, lasting and stable, and shewing their Substances to be thus durable, he says that the whole Circumgyration is unitedly performed about these.* Thus *Proclus*, whose Words in my Opinion are more specious and popular, than true and accurate. For notwithstanding I am not of his Sentiment concerning these Indivisibles, I do not think that *Superficies*, *Lines*, or *Points* possess any separate Existence or proper Efficacy from themselves; or are otherwise distinguished from a solid Magnitude, than in Thought; but I rather imagine, that in Reality there is only one Species of Magnitude, which may be sundry Ways extended, differently divided, and undergo the various Considerations of *Thicknes*, *Breadth* and *Length*, and affords to our Reason a fit Cause or Occasion of devising that Distinction of Magni-

(m) Τά τε γὰρ κέντρα κατ' ἐέργειαν, &c.

tude,

tude, as it were into three Species, so very useful and accommodate to this Science. But these Things may suffice to be spoken concerning the Termination of Magnitude. For a more opportune Place will offer itself for treating about its particular *Figuration*.

II. *Of the Extension of Magnitude.*

This is succeeded by *Extension*, whereby is signified that the *Terms* of Magnitude are not immediately conjoined or do coexist, but have something interposed between them. For the Reason of a *Term* or *Extreme* requires, that something be supposed to be comprehended within the *Terms*. (*n*) *Extremes* (says the Philosopher) *cannot consist together; for that which has no Parts can have no Extreme, for an Extreme is different from that to which it is the Extreme; and elsewhere; a Term is one Thing and that to which it is the Term another.* We cannot indeed conceive any Magnitude, but as *extended*, and having Bounds distant by some Interval: We cannot conceive a *Line* but as a Path drawn between two Places as *Extremes*, not a *Superfice* but as a Floor lying within its Limits, nor a *Body*, but as a Vessel, or Chamber, containing something within its Walls. For Experience will suggest to us such Representations and Ideas of Magnitudes. In like Manner some Sort of *Extension* agrees with analogical Quantities after their Way. For between that *Force* which is capable to lift up one Pound, and that which can raise Ten Pounds, there lies a mean Power capable of elevating two, three, &c. Pounds; from whence a Pound is *extended* after its own Manner. And a certain *Duration* intercedes between the first

(*n*) *Phys.* VI. 1.
L 2

and last Instants of a Year, a Month, a Day, or an Hour; according to which is the *Extension* of *Time*. Also there lies some Mean between the Beginning and End of *Motion* correspondent to the Space moved over. Lastly, the *Extension* of *Number* is the same with the Magnitude which it denominates and represents, *viz.* The Two, whereby a Line of two Palms is expressed is *extended* to the Length of two Palms; the Two whereby a Field of two Acres is denoted is stretched to the Breadth of two Acres. Since therefore it sufficiently appears by our Conceptions taken from Experience that all Magnitude and Quantity is some how *extended*, it will be lawful for Mathematicians to suppose this, and draw what Consequences they can from such Suppositions: and such Hypotheses as these following ones will be of Force. *Ex. gr.* *A mean or middle Line may be assumed between two assigned Points: A mean Superfice may lye between two expounded Lines: Some interjected Body may be conceived between two extreme Superficies: Some mean Time may be understood between two Instants: Some intercepted Weight may be placed between two Moments: Some intercurrent Motion may be directed between two Terms.* And every Supposition thus assumed is lawful. And so much for *Extension*.

III. Of the Composition of Magnitude.

The next Affection of Magnitude, which follows its *Extension*, is its *Composition*, *i. e.* that Magnitude contains within it or consists of different Things. For because it is extended, and its Extremes are distant from one another, therefore the *Whole* is not in the same indivisible Place; whence different Things may be assigned in it; and consequently it is compounded of different

different Things, *i. e.* of *Parts* : For a Magnitude is called a *Whole*, as it is compounded of different Things contained in it, and those different Things are called *Parts*. And by equal Reason, since the said *Parts* taken singly are not the *Whole* taken conjunctly, (for if they could be the whole Magnitude taken conjunctly, they would coincide with the Extreme of the *Whole*, or with the Extreme of the *Part* adjacent to it, and consequently there would be no other Mean nor *Part*) therefore in like manner different Things may be assigned in it, and consequently it is compounded of other *Parts*, and these again of others, and so on *ad infinitum*, *i. e.* as long as we can imagine it to be composed of *Parts* still more minute. Whence it follows, that every Magnitude consists or is constituted of Magnitudes homogeneous to itself, a Line of Lines, a Superfice of Superficies, and a Body of Bodies ; but not a Line of Points, or a Superfice of Lines, or a Body of Superficies. For Points *ex. gr.* in respect of a Line, except in the Cases mentioned above, are nothing else but Negations of further Extension, and do scarce obtain any Thing positive ; and moreover as Terms they denote something interposed, as not being able to cohere immediately of themselves ; and the Whole of a Line, whatsoever it be, is imagined between them. They are also indivisible, and therefore, if two be supposed to lie one upon another, they will mutually touch each other through the *Whole*, *i. e.* they will coincide and coexist, and consequently do constitute nothing which has Extremes or is extended. So reasons the (o) Philosopher, speaking of Atoms ; *For since they touch one another in one Magnitude, and the Magnitude is one and continued, and they are taken together, they do make*

(o) De Gen. & Corrupt. 1. 1. c. 2.

the Whole no greater, because, though the Whole be divided into two or more Parts, it becomes no less than before : So that if they be all joined together they will make no Magnitude. And as these are in respect of a Body, the same is a Line in respect of a Superfice. The same Way does a Time consist of Times, not Instants ; a Motion of Motions not indivisible Tendencies : a Velocity of Velocities, and a Weight of Weights neither of Degrees nor Impetus's absolutely the least : a Number of Units, and Units of Fractions, not Cyphers. Hence also it is apparent, that a Point may be any where at pleasure assumed in a Line, a Line and a Point in a Superfice, and a Superfice a Line and a Point in a Body. For because some of the infinite, or rather indefinite (*i. e.* more than any Determinate Number of) Parts of a Body begins or ends every where, therefore its *Term* every where is accounted a Superfice, a Line terminating any Part of that Superfice, and a Point any Part of that Line. Nor is this contrary to common Sense, since we often appeal to that, as being the Test and Index of Experience, which, as has been often inculcated, is the Foundation of Hypotheses. For we can have no possible Conception of any Magnitude, but as compounded of *Parts*, nor of these *Parts* but as somehow extended and consequently made up also of *Parts*. A Thing perfectly uncompounded obtaining a positive Place in Matter as it is beyond all Sense, so does it exceed all Imagination. It is therefore lawful for Mathematicians to suppose this *Composition*, and whatsoever immediately follows it. Such Suppositions, not to use Repetitions, as I shall subjoin in treating of the following Property, which has the closest Connection with this.

Of the Divisibility of Magnitude.

Divisibility is the inseparable Companion of *Composition*. For since, as was just now shewn, Magnitude is compounded of Parts really distinct; these may exist asunder, at least be considered separately, *i. e.* they may be really or mentally divided or resolved into Parts. Wherefore the Philosopher raises from hence the Definition of Quantity; *To be that which may be divided into those Things which are in it, each Part of which (supposing the Parts to be only two) or every one of which (if more) is capable to exist and that determinately (p).* Consequently *Divisibility* being essential to Quantity, therefore that may be conveniently defined from it. And this aptly agrees with the common Conceptions of Men. For some assert an indivisible Quantity in Words, but none I believe can paint its Image in the Mind: Extension vanishes with Divisibility, and the whole with its Parts. The Philosopher deservedly enquires (q) *What that is which cannot be divided?* Why Nothing at all. This prevails in all Magnitude; and by a like Reason in all its Parts also: As All do consist of Parts, so may All be resolved into one kind of Parts or another. There is no Part in any kind of Magnitude, which is absolutely the least. Whatsoever is divided into Parts, is divided into Parts which are again divisible. *I say, says (r) Aristotle, whatsoever is continued is always divisible into Parts again divisible.*

I am not ignorant, for few can be ignorant, how difficultly this Doctrine is admitted by some, and entirely rejected by others; and with what

(p) Met. IV. 13.
(r) Phys. VI. 1.

(q) De Gen. & Corrupt. 1. 2.

Stiffness the Controversy about the perpetual *Divisibility* of Quantity, and *Composition* of Magnitude is every where treated, *viz.* *Whether it do consist of Parts indivisible, or homogeneous*; which I am sensible is involved in many Difficulties, and obnoxious to many contradictory *Querks*, especially by Reason of the intervening Conception of Infinity, which is not perfectly comprehensible to us. But I have no Mind at present to turn over so many Trifles, to untie so many Knots, and to enter upon a trite Question so vexatious, prolix, and perplexed; the accurate handling of which would fill a whole Volume, and require more Care and longer Delay, than would at this Time be worth the while to lay out upon it. It may suffice that the perpetual *Divisibility* and *Composition* of Quantity out of common homogeneous Parts, as we have intimated, does answer well to the Ideas of Men; and that most of the excellentest Philosophers have supposed and defended it. Among whom in the first Place we may reckon *Plato*, if *Aristotle* be to be credited. *For also Plato*, says (m) he, *does therefore make two kinds of Infinites, because he thinks there is an infinite Procedure both in Augmentation and Diminution.* Next, *Aristotle* himself not only asserts but strongly proves it in many Places. *vide Phys. Aufc. VI. I. De Gen. & Corrupt. L. 2.* and in a particular very learned Book concerning indivisible Lines. Again the whole School of the *Stoics*, and among them the most acute *Chrysippus* is said to have given their Suffrages to this. Also among the modern Philosophers the most subtle *Cartesius* gives his voice, and not only well nigh demonstrates that Matter is infinitely divisible, but that it actually is divided; which he does by an Argument in

(s) *Phys. IV. 6.*

Physics fetched from the continued Motions performed along the unequal Interstices of excentric Circles.

Add to these the necessary Consent of all Mathematicians ; for though they scarce do any where openly suppose this, yet they often assume it covertly ; and except it be true, most of their Demonstrations must fall to the Ground : They assume it covertly, I say, as in the Definition of a Right Line, whether it be said to lie evenly between its Points, or be defined to be the shortest of all Lines that can be drawn from one Point to another. For how can a Line consisting only of two Points lie at all between its Points. And if, in Condescension to our Adversaries, the Semidiameter of a Circle be supposed to consist only of three Points, it will be equal to the side of an Hexagon inscribed within that Circle ; but the sixth Part of the Circle's Circumference will not reach to four Points, for then the whole Circumference would consist of twenty and four Points, and consequently would be four times its Diameter, contrary to the manifest Demonstrations of *Archimedes*, and even to common Sense itself, whereby the Circumference of a Circle is known to be lesser than the Perimeter of its circumscribed Square : And if the sixth Part of the Circle's Circumference do not reach to four Points, then according to the Hypothesis of the Advocates for Indivisibles, it can by no means exceed three ; and therefore it will not be greater than its Subtense, nor consequently will a Right Line be the shortest of all Lines which can be described between the same Points. And the like Difficulty will follow, if the Semidiameter of a Circle be supposed to consist of five Points ; for the Circumference of sixty Degrees will not reach six Points, because then the whole Circumference would

would contain thirty and six Points, *i. e.* it would exceed three and a half of the Diameter, which is again contrary to common Sense, as may be easily demonstrated. Which Consideration alone may suffice to overthrow the contrary Opinion, at least it plainly declares its Repugnance with Mathematical Principles. Also since a Right Line is supposed to be drawn from a Point to a Point, how can that consist with Indistance, or the immediate Coherence of Points? Moreover when it is assumed that two Right Lines after Concourse do immediately separate, or depart, from one another, and cut not one another any where but in one Point, nor have any common Part beyond the Point of Intersection, and the like; these things are manifestly destroyed by the Supposition of Indivisibles. For if the Circumference of a Circle be supposed to consist of any Number of Points to every one of which *Radii* are drawn from the Center, it is very evident, that the Circumferences of more concentric Circles will consist of the same number of Points with the former, and consequently are equal to it, which is most absurd: Or otherwise these *Radii* do touch, meet, or intersect one another in some Place else than the Center. And as to Geometrical Conclusions, How can a Right Line be bisected consisting of unlike Points? How can any Line be divided into the same Number of equal Parts which are supposed in any other? How, if the Legs of a Triangle be any way unequal, can Parallels be drawn to the Basis through any Points of the greater, which passing through the lesser Leg do not coincide, intersect, or touch one another, contrary to the Nature and Definition of Parallels? And if the Legs be much greater than the Basis, how can Parallels grow uniformly or keep the same Proportion with the Parts intercepted to the Vertex of the Legs, so as not by
much

much to exceed the Bases, which yet are sensibly lesser? How, in the same Right Line indefinitely produced to any Number of Centers (suppose ten Millions, or as many as you please) can Circles described through the End of the said Right Line touch one another only in one Point: According to that most manifest Precept of Geometry, whence it plainly follows, that a Right Line, how small soever and near the Point of Contact, if it cut the Circumference of these Circles, it cuts it in an indefinite Number of Points, and consequently in an Infinity of Points in Power? How, according to our Adversaries, can a mean Proportional be found between two Right Lines, one *ex. gr.* consisting of seven and the other nine Points; or how can a third Proportional be exhibited to the same seven and nine? For if, for finding the Mean, a Semi-circle be made upon those Lines joined together as a Diameter, and a Perpendicular be erected from the common *Term* of the Segments, that Perpendicular will not be the Mean Proportional required between the said Right Lines, because there can be no such, according to the contrary Supposition. How does not this entirely destroy every Incongruity of Magnitudes, which is shewn by Geometricians in so many Examples, and supported with so many Demonstrations? Since a Point is the common Measure of all Magnitudes, and every one Magnitude is to another as a Number of Points to a Number of Points, if Lines consist of Points, Superficies of Lines, and Bodies of Superficies. How is not the whole Doctrine of Asymptotical Lines thus effectually overthrown; a Doctrine indeed wonderful, but no less certain and evident than any other Part of Geometry, which either invincibly confirms the infinite Divisibility of Magnitude, or coincides together with it; since it is clearly demonstrated by it, that the
smallest

smallest Line is not exhausted by a continued Decrease *ad infinitum*, nor made equal to a given Line but very little greater, by a continued Increase *ad infinitum*? How lastly is not all the Difference also of Motions, as to Velocity, taken away by this means. *Ex. gr.* If a moveable Point run through five Points in one Time, how can another perform the subduple, subtriple, or subquadruple of that Space in the same Time, when the Whole is not capable of being divided into these Parts? Nay, I could devise and produce even an Infinity of such Instances, whereby it may be proved from this Assertion of Composition out of Indivisibles, that the whole of Geometry is altogether subverted and destroyed, having nothing left in it sound and solid: And thereby a huge and deplorable Ruin, Confusion, and Inconsistency is brought upon this most Divine Science; whose Principles (*t*) notwithstanding, besides their Evidence and the Rigour of its Reasonings, are so firmly established, as well by their wonderful Consonance one with another which could not happen if they were false, as by their perpetual and exquisite Agreement with Experience; so that the Poles of the (*u*) World will be sooner removed out of their Places, and the Fabrick of Nature destroyed, than the Foundations of Geometry fail or its Conclusions be convinced of Falsity.

But we must leave this Question, and I shall briefly observe to you, that all the principal Arguments, which are brought against the perpetual Divisibility of Quantity, are either mere begging the Question, or depend upon false Suppositions, or lastly have no Relation at all to the Matter. *Epicurus* objects for the Patronage of his Atoms, that if the Parts of Magnitude be infinite, it is unintelligible how a finite Magnitude can consist of

(*t*) *Arist. de Cælo* I. 5.

(*u*) *Arist. Eth.* I. 8.

such

such Parts. And what is this, but to beg the Question, or conclude a Thing from itself? For it is sought, whether a finite Magnitude (we speak not of an infinite one) can have an Infinity of Parts. Our Adversary says it cannot be, the Thing is unintelligible. But he had more appositely required an Explication of the Manner how it may be done, than to have concluded that it cannot be done. To which Question I might answer, that it is indeed contrary to Reason for a finite Magnitude to have any determinate Denomination of Parts (*ex. gr.* its Hundredth or Thousandth Parts) infinite, nay it is a Contradiction for it to have more than a Hundred or a Thousand of such Parts; but I do not see any Contradiction in its having more than ten Millions of Parts, or more than can be expressed by any Number, nay, rather I conceive it to be very agreeable to Reason. It is certain that as whole Numbers may be infinitely encreased by Addition, so on the contrary may Fractions be infinitely decreased by Division, *viz.* as a Number may be conceived greater than a Thousand, so may a Part the same way be conceived below a thousandth Part; it is the Sign of Magnitude, to which they correspond, to encline equally on either Side to Infinity. Nay it is plainly taught and demonstrated by Arithmeticians, that an infinite Series of Fractions, decreasing in a certain Proportion, is equal to a certain Number, or to Unity, or to a Part of an Unite; *ex. gr.* that such a Series of Fractions decreasing in a *subsesquialter Proportion* is equal to *Two*, in a *subduple Proportion* to *Unity*, in a *subtriple* to *one half*; from whence it is not inconsistent for something finite to contain in it an Infinity of Parts: especially since nothing agrees with Number, which does not with more right agree with Magnitude, which Number represents and denominates. And indeed if we do but consider, that

that as the Multitude of Parts encreases so does their Magnitude reciprocally decrease, it will be no Difficulty to imagine what way a finite Thing may consist of infinite Parts. So that if it have three Parts each of these is no more than one third Part of the Whole, if four, one fourth, &c. their Smallness compensating the Multitude. But *Epicurus*, or *Lucretius* in his Name urges :

Præterea nisi erit minimum, parvissima quæque
Corpora constabunt ex partibus infinitis.
Ergo rerum inter se summam minimamque
quid esset ?

*Besides if we in Matter don't admit
Some Particle, than which none can be less,
Then the minutest Bodies will contain
Parts without Number ; ———*

Right so far, but what's the Consequence.

————— *and of Consequence*

*No Diff'rence will be found 'twixt Great and
Small.*

He imagines that, if our Hypothesis be admitted, the least Quantity will equal the greatest, a Grain of Poppy will be as much as the whole Universe, and a Fly no less than an Elephant ; because those, as well as these, do contain infinite Parts. But this way of arguing proves nothing : For what hinders a small Thing from having as many lesser Parts as another greater Thing has greater ; and that a Shilling may be distributed into as many Pence as a Pound into Ounces ; or that a Foot may contain as many Octants as a Mile itself does Furlongs. And why may not the same Proportion which is between the Globe of the Earth and a Grain of Sand, be between that Grain of Sand and some other minute Particle of Matter, *i.e.*
as

as often as the first contains the second, so often does the second comprehend the third? Since GOD is able to create a World in all Respects like this, which may be no greater than the minutest Piece of Dust or Sand. Therefore both what is greater and what is lesser may consist of infinite Parts, only the Parts of that will be greater, and of this lesser; *viz.* so much lesser in Proportion, as this Whole is less than that Whole.

But again they insist that at least, according to our Assertion, it must follow that Infinites may be unequal; because the Number of Parts in a Line of two Feet will be twice as much, as an infinite Number of Parts in a Line of one Foot, since whatsoever the former Number be, it is most evident, it must contain this twice; but (say they) it seems absurd for an infinite to be exceeded, contained, or multiplied. I answer, that the Question is again begged in this principal Argument of our Adversaries: *i. e.* they conclude the same thing from itself expressed in other Words. For an infinite Number denotes nothing else, but that the Thing to which it is attributed may be divided or conceived to be divided *ad infinitum*; which we assert to agree as well with the Line of one Foot, as that of two; notwithstanding one is double the other: This on their Part they deny in other Words, but bring no new Argument to support their Opinion. Number indeed (as has been often inculcated) whether finite or infinite has neither Equality nor Inequality of itself, in respect of another Number, unless so far as each Number designs and represents a Magnitude of the same Kind; wherefore, to say that this infinite Number is greater than that infinite Number, and to pronounce this absurd, is all one as to say that this Magnitude which is conceived to be divided *ad*
infinitum

infinitum is greater than that which is also conceived to be divided *ad infinitum*, and hence to conclude the Thing absurd, *i. e.* to deny our Position, but not to oppose it with any new Device. Besides I affirm, that it seems no way absurd for an Infinite to be contained within an Infinite, *i. e.* for an infinite Magnitude to be contained within an infinite Magnitude, or an infinite Number within an infinite Number ; for if a Right Line be supposed to be extended infinitely in Space, which is imagined by the most Part to be immense, it will doubtless contain an infinite Number of Feet, an infinite Number of Paces, and an infinite Number of Furlongs : Also an infinite Right Line will be oftner contained in an infinite Superfice ; and this Superfice again innumerable Times more in an infinite solid Body. And the same way may infinite Years, more infinite Days, and yet more infinite Hours, and lastly most of all infinite Moments, be easily conceived in an eternal Duration. You will say these Positions are impossible and absurd. I answer, since the Adversary builds his Arguments upon the Nature of Infinite, it may surely be lawful for us to suppose it, and though the Position of the Thing itself may perhaps be impossible, yet the Consequence is manifest and perceptible ; *viz.* that it is no where repugnant (as they would have it) with the Nature of an Infinite to be contained in another Infinite : as it is sufficiently evident that to have Feet or Horns is not repugnant to the Notion of an *Hircocervus* (*i. e.* a Creature half Goat half Buck) though it be naturally impossible for such a Creature to exist. And the *Epicurean* Advocates of Atoms do own as much themselves : What else means their *Vacuum* infinite in Magnitude, and their *Atoms* infinite in Multitude, which *Plutarch* relates to have been taught by *Epicurus* himself? And the same is attested by *Lucretius*.

—patet

————— patet ingens copia rebus
 Finibus exemptis in cunctas undique partes.

*A Multitude immense extends itself
 To every Part of the unbounded Space ;
 There being no Limits to be set to Things.*

Which being supposed it plainly appears that an infinite Number is in Fact comprehended within an infinite Number, and an infinite Space within an infinite Space. For in an infinite Number of Atoms are contained an infinite Number of Octonaries, a more infinite Number of Quaternaries, and again a more infinite Number of Pairs, and an infinitely more infinite Number of Unites. And the same of Spaces.

Lastly *Zeno* objects against our Opinion, that a Space consisting of infinite Parts cannot be passed over successively, and consequently he thus takes away Motion from the Nature of Things. I reply in a few Words, that this will follow rightly, if the moveable Body be supposed infinitely slow; but if it have any Velocity, that will answer to some determinate Part of Space, which will consequently be measured by the moveable Body in a Time assigned.

I observe that they who would have Magnitude constituted of a finite Number of Indivisibles (which Opinion is still more repugnant to the Laws of Geometry) do yet agree in most Things said against the Composition from Indivisibles. With whom perhaps may be reconciled (since it differs no otherwise than in the Manner of Speaking) the Opinion of *Galilæus* and others following him, who think it to be compounded of an infinite Number of Atoms. But I pass by this Opinion, for if I should minutely examine all Things that occur

cur to my Thoughts, my Discourse would grow to an immense Bulk. I therefore leave many Things to be corrected by your more mature Judgment, and supplied with greater Care.

But not to prolong this tumultuary Discourse *ad infinitum*, I deny not but it is difficult to be understood, how every single Part can be divided so as all not to be actually reduced by the Division to Indivisibles, or to Nothing or what is next to Nothing: Nor yet do I think, by reason of the Imperfection of the Mind of Man and the Smallness of our Capacities, that therefore the Truth is to be deserted, when proved by so many evident Tokens, and supported by so many strong Arguments. *It is indeed, says Aristotle, contrary to Reason to submit to, or sink down under our Infirmary, because we cannot repel all Instances; and cast ourselves into greater Errors, because we are not able to free ourselves from lesser Difficulties.* To whom *Cartesius* (*) agrees in a like Prudence. Though we are not able to comprehend how this indefinite Division can be performed, yet we ought not therefore to doubt, but it may be performed; because we clearly perceive it to follow of necessity from the Nature of Matter, a Thing most manifestly known to us, and we do also perceive it to be of that kind of Things, which cannot be comprehended by our Minds, as being finite.

It follows therefore that every Quantity is compounded of Parts that are compounded, and may be divided into Parts that are again divisible, and consequently that Mathematicians may build Hypotheses upon these Foundations. Such *viz.* as these and the like: *From any greater Magnitude may be subtracted one equal to any lesser: Between two homogeneous unequal Magnitudes may be assumed a*

(*) Princip. II. 34.

Mean Magnitude of the same Kind: A Point may be assumed any where in a Line; a Point and a Line in a Superfice; and a Point, Line, and Superfice in a Body: Every Magnitude has its homogeneous Parts capable of being denominated by any Number, ex. gr. its Tenth, Hundredth, Thousandth, &c. Parts; nor is it contrary to Reason, if, for Speculation's sake, they be supposed to be any how divided, &c. But it is not my Design to enumerate all Hypotheses, but only to open their Fountains. Other Attributes of Magnitude remain, which Time will not permit me to pursue farther at present.

LECTURE X.

Of Space, and Impenetrability.

SINCE the Thread of my Discourse has led me, for the sake of Mathematical Hypotheses, to treat of the more common Affections of Magnitude; and since I have already spoke something (little indeed considering the Dignity of the Subject, but enough for our Design) concerning some Things which first offer themselves, *viz.* the *Termination, Extension, Composition, and Divisibility* of Magnitude; it now follows, that I should touch upon what remains, *viz.* its *Occupation of Space, Determinate Position, Mobility, Mensurability, Proportion,* and whatsoever else occurs from whence Mathematicians do, or lawfully may, draw Hypotheses suited to their Ratiocinations.

In the first Place, it is wont to be attributed to Magnitude, that it *occupies, or fills Space.* But it is difficult to explain what this *Space* is. For if we either attend to vulgar Conceptions, or examine

the more subtle Sentiments of Philosophers, it is not easy to determine whether there really is any *Space* distinct from Magnitude or not; the Opinions on each side seeming both to depend upon very specious Arguments, and be pressed with weighty Difficulties.

On the one Hand, these Arguments seem to make it sufficiently plain, that there is really no such Thing as *Space* existing separate from the Quantities of Things. And that first, because, if it be unproduced and independent, it must consequently be also eternal and immense (for were it not (say they) that such a Thing is for the most Part conceived and supposed by the Assertors of real *Space*; if such a Thing be not, then every Reason will fail upon which it is supposed, as will appear to any one who weighs the Causes of framing it;) but for any Thing to partake of the singular Attributes of the Divine Nature, such as not to be created nor dependent upon God, seems contrary, as well to right Reason, as Religion. Again if we examine the Idea of *Space* whatsoever it be, we seem to apprehend nothing by it but a certain Extension and indefinite Capacity; which, since they are Properties of Magnitude itself, do argue no Difference of Space from Magnitude; for why should that differ in the Thing, which agrees in the Properties? And this is not only the Argument of *Cartesius*, but of *Aristotle* himself. *If (says the Philosopher) the Magnitude of Things have nothing in itself different from Space, then wherefore is the Bulk of a Thing distinguished from its Space?* Moreover if *Space* be any Thing different from Magnitude, we may enquire to what Classis of Things it is to be referred: For every Thing either subsists of itself, or is an Accident to another Thing; but neither of these seems to agree with *Space*. The Patrons of *Space* do not exalt it to the
Dignity

Dignity of a Substance, nor will the Thing itself bear it. Neither is it an Accident, because it is extrinsic to all Substance; since it is not carried about with it, but remains, though that be taken away, and depends upon no other Thing. I pass by the Device of *Zeno*: That every Thing is somewhere, therefore if *Space* be any Thing distinct from other Things it must exist somewhere; whence there will be a *Space* of a *Space*, and another *Space* of this second *Space*, and so on infinitely (as (y) *Aristotle* observes) which is ridiculous. By such Arguments as these is the real Diversity of *Space* from *Magnitude* opposed: but it is defended from Arguments which are equally strong in Appearance.

For *first*, if we appeal to the common Conceptions of Men, the Notion of a *Space* distinct from Things does seem to be either innate or acquired. *All Men* (says (z) *Aristotle*) *do in Thought separate the Ubi of Things from their Esse.* The *Vulgar* are accustomed to imagine that there is some common *Substratum* to all Things, which is infinitely extended, and circumscribed within no Limits; which is perfectly penetrable, and easily admits every Thing within itself, not resisting the Entrance of any Thing; which receives the Successions of moveable Bodies, determines the Velocities of Motions, and measures the distances of Things; which is immoveably fixed, has none of its Parts tied to any Thing, nor can possibly be any where transferred from where it is; which lastly is a *Receptacle* of immense Capacity, or as the (a) *Philosopher* speaks *an immoveable Vessel*, containing within it all the Things that either are, or can exist. Such is the Notion of *Space*, which is engraven in the Imaginations of all Mortals. And very many

(y) *Phys.* IV. 3.(z) *Ibid.* IV. 1.(a) *Ibid.* IV. 6.

Things beside seem to argue the real Existence of such a Thing, as well as this Consent of the Imagination : To make the Force of which apparent and effective, certain Positions or Assertions are to be laid down, whereby the Arguments brought for the Reality of *Space* are supported.

First then Matter is not infinitely extended ; at least, which is enough for our Purpose, it is not so of Necessity. For from whence can it have this Necessity ? Is it from itself ? This is impious, since the sacred Writings do often expressly ascribe the Origin of all Things to God : *All Things* (says (d) St. Paul) *were created by him and for him.* And thus sung the four and twenty Elders, (e) *For thou hast created all Things, and for thy Pleasure they are, and were created.* Again, as the Evangelist (f) St. John expresses it, *All Things were made by him, and without him was not any Thing made that was made.* For all those Things, says the Prophet (g) *Isaiab, hath mine Hand made, i. e.* all Things whatsoever without any Exception : And innumerable such other Expressions occur every where in Scripture. Nor is there any Reason why we should believe Matter to have an infinite Substance necessarily of itself. Is it then from God ? Who imposed this Necessity upon him who is a perfectly free and independent Agent, that he should attribute Infinity to Matter ? How does it appear to have been attributed to it ? I do not dispute whether or no he is able to do so, for who can assign Limits to the Divine Power ? But it seems far more credible that, as he has limited the Powers of other Things, so he has appointed certain Bounds to Matter. The *holy Scriptures* do seem plainly to attest as much, (b) *Behold* (says

(d) Eph. iii. 9.
(g) Isa. lxvi. 1.

(e) Rev. iv. 11.
(b) 2 Chron. ii. 6. & vi. 18.

(f) Joh. i. 3.

the most wise King, more than once) *the Heaven and the Heaven of Heavens cannot contain thee, i. e.* the whole Universe is too narrow to exist with God; he transcends the utmost Bounds of Things, and consequently Matter is not in fact extended *ad infinitum*, much less is it so of Necessity.

To this it is replied by (i) *Cartesius*; *It is necessary for Matter to be infinitely extended, for this Reason, because we conceive its Bounds everywhere; we do not only imagine certain Spaces to be extended indefinitely beyond ourselves, but they are moreover truly imaginable; i. e. we perceive that they are real, and consequently that a bodily Substance indefinitely extended is contained in them; since the Idea of that Extension, which we conceive to be in all Space, is altogether the same with the Idea of a bodily Substance.* But this Argument seems to contain in it more of Subtilty than Solidity. For *first*, no Body either does or can conceive Matter to be actually infinite; but to conceive it to be indefinitely extended, is the same as to imagine it to have no Terms or certain Bounds; as the vulgar Part of Mankind do think the Surface of the Earth to be infinitely extended; or as one standing upon the Shore thinks the Sea to be encompassed with an uncertain Bound; or as we conceive the Grains of the Sand of the Sea to be indefinitely many. Moreover because we can imagine certain Spaces beyond any determinate Bounds; it by no means follows that Matter does actually exist beyond. However it may be probably gathered that it therefore may exist, because whatsoever we conceive as evidently possible, that may be effected by the Divine Power. But who in his right Mind will deny, that we may imagine innumerable Things, which neither are nor ever will be? Nothing is repugnant, and

(i) *Princ. II. 21.*

we may easily imagine with the vulgar, that the Earth reaches to the utmost Bounds of Heaven and the farthest Limits of the Universe: we may suppose in our Minds the Sun to be a thousand Times greater, the Moon many Parasangs higher; the Stars vastly more numerous, and innumerable other Things, which are by no Means impossible, nor altogether absurd; but are these Things therefore true in fact? No certainly, they are no more than so many Dreams or Deliriums of sick Men. Imaginability then does at most only prove the Possibility of a real Thing, but no where its actual Existence. The World is not proved to be actually infinite from the Imagination, but only to be greater in Power than any finite, (*i. e.* determinately finite) Thing.

But to be satisfied how very much *Cartesius's* great Subtilty has failed him in this Case, let us search and weigh a little the Origin of this our Imagination of *Spaces* beyond the World, and we will certainly find it like most other Things, to be derived no otherwise than from the Senses. For since we scarce attain any Thing by any Sense, but we still experience something equally sensible by proceeding beyond it; especially when lifting up our Eyes to Heaven we behold the vast Chasm on every Side contained within no perceptible Limit, but running forth into Regions unknown to us; hence an Occasion is offered of describing in our Fancy a certain immense or indeterminate Gulph of heavenly *Space*, in which the Clouds are suspended, the Winds blow here and there, and the Stars seem to swim like so many Fishes: from which Sensation notwithstanding, or Imagination, it seems very absurd to infer any Thing concerning the true Extent of the Universe, whether it is finite or infinite. For every Sensation is of Things particular, and from the
the

the Existence of a particular Thing, we may conclude that something like it may exist, but not that it actually does exist, as has been sometimes taken notice of before.

I say nothing as to the Parity of Reason in attributing *Eternity* and *Independence* to Matter, as well as a *necessary Infinity of Extension*; for as there is some Space beyond any Limits of the Universe, so has it been before any Beginning. We are wont to have the same clear Imagination of some Time after the End of any Time, and consequently by this way of arguing, Matter may be demonstrated to be necessarily eternal, whence it follows that it is also independent: which Properties notwithstanding of the Divine Perfection, it is most dangerous to attribute to any other than the great God himself; and is in the highest Degree to be shunned by a Christian Philosopher. It may be therefore taken for granted, that Matter or Body is not altogether unbounded; at least it is not so necessarily. Let this be first supposed.

Let it be also assumed, *secondly*, that it is in the Power of God to augment or diminish the Matter that now exists, according to his Pleasure, *i. e.* to create, or reduce to Nothing, what Portion of it he pleases. Faith commands, and Piety compels us to admit this; nor does Reason oppose, but rather defend and confirm it. For since we can conceive Matter to be larger than any Thing determined, therefore nothing hinders, nay it evidently follows from thence, that God can cause it to be so. But if it may be enlarged, by the same Power it may be diminished; and the Web which he hath newly wove, he can with the same Ease unravel. And because we can imagine Matter more contract, nay suppose it Nothing at all, it is therefore in the Divine Power to perform it,

Moreover,

Moreover, *thirdly*, it is most easy to conceive, and ought by no Means to be denied, that God can preserve every Thing in its present State and Situation, so as not to be intrinsically changed by any extrinsic Accidents, much less to have its Nature entirely destroyed; *viz.* that a Right Line, a plain Superfice, the Circumference of a Circle, the Roundness of a Sphere, and such like Things may remain, whatsoever happens without them, *i. e.* though all circumjacent Matter be any how changed, taken away, or annihilated. Which Things being lawfully supposed and laid down, the Reality of *Space* distinct from Magnitude does seem to be many Ways established.

As *first*, since Matter may be finite, and God is infinite in Essence, he must subsist beyond the Bounds of Matter, otherwise, he would be enclosed within its Limits or some Way bounded, and therefore could not be infinite. Therefore something is beyond, *i. e.* some sort of *Space*. And if God do not exist beyond the Bounds of Matter, our Imagination would be capable to conceive a Place where he is not; and consequently would in some Sort transcend the Manner of the Divine Existence; whence it would follow, that we could not apprehend or conceive God to be immense.

Next, God can create other Worlds beyond this, as also we can imagine them to be created, not no where, but some where; there will therefore be given some *Space* wherein they may be placed and exist. And God will also be present in these new produced Worlds, yet without being the least affected with Motion himself (for all kind of Immobility and Immutability is an undoubted Attribute of the Divine Perfection) which can no otherwise be understood, than by conceiving him to have before been present in the *Space*, where they
they

they are now repositèd. Therefore the Conceptions which we have, or ought to have, concerning the Divine Infinity, Power, and Immutability do involve some distinct *Reality of Space*.

Moreover the material World, from the Hypothesis which we have asserted, will be limited and endowed with some Figure, and consequently may be supposed of any Figure. Let it therefore be Spherical; and because it may also be lawfully done, let some other spherical World, or Body, be in like Manner supposed to be contiguous to it, which will touch the former in only one Point; therefore there will lie some Mean, *i. e.* some *Space* between the other Points of the Spheres. For let any two Points be assumed in the Superfice of the contiguous Spheres without the Contact, I say some Space will lie between these; If you deny it, then these two Points will meet one another, contrary to a most clear Demonstration in Geometry.

Also let the two Centers of the Spheres be connected by a Right Line passing through the Contact as Geometry also teaches and proves; and let two Radii be understood to proceed from the Centers to the said Points without the Contact; then because, according to the Opinion of our Adversaries, the said Points are contiguous, they will constitute a Triangle of three Right Lines, two of whose Sides will be equal to the third, in like manner contrary to a most clear and certain Theorem of Geometry. Again let the Matter, which goes to constitute two concentric Spheres, be supposed in any Place, and let the interjacent Matter between their Superficies be annihilated, or removed out of the Way, (which as has been supposed may be done by the Power of God) then these Superficies, if no *Space* come between, will meet one another, though the one were a thousand times greater than the other: For we may suppose
from

from what has been said that both the spherical Surfaces do retain their Magnitude, the Evacuation of the middle Body, which happens extrinsically and changes nothing within them no ways hindering it ; the Divine Power some how preserving their Magnitude and Position. In the same manner if what is between the Vertex and Basis of a Pyramid be taken away, since there is no Space left, therefore the Point of the Vertex will lie next to all the Points of the Basis, and consequently will be congruous and equal to the whole. These and innumerable such other Things do seem to follow, from the Denial of *real Space*, which are no less repugnant to the common Conceptions of Men, than the Principles of Geometry.

Besides it seems somewhat harsh to suppose the Matter of the Universe entirely immoveable, as to the whole of it, or to imagine that nothing exists any where, except one solid Sphere ; because such a Sphere could not indeed be transferred by God, nor (to use the Words of *Plato*) admit a *Peripheron* or Rotation about its Axis, which the taking away of Space does manifestly infer. For since in every such Motion, the Parts retain the same Situation to, and the same Distance from one another, howsoever the Whole be carried ; it can be no otherwise conceived to be moved, but from a successive Change of *Space*, viz. so as one Part may enter the Space left by the foregoing one ; from whence by the Denial of Space, we take away the Mobility of Matter. *Aristotle* in a certain Place observes something like this, where he says, *That Motion alone gives Occasion of Disquisition concerning Place or Space (as scarce being capable of Conception without the Position of Space) and the Heaven above all Things seems especially to be in Place, because it is most of all moved : nor yet is this any how varied (in respect of the first or principal diurnal Motion,*

tion, which the Philosopher seems to respect) according to the Situation and Distance of the Parts, but as the Whole is carried about. It is therefore so far moved, or not at all moved, as its Parts do change their *Spaces*; and those Parts which are now at the Rising of the Sun, do anon, reach the height of the Meridian, and as soon as they have passed that do immediately decline to the Westward. Nor will it here suffice *Cartesius* to distinguish Action from Motion, since no Effect of this Action can be imagined without a change of Space.

I will yet add one small Argument to these: I ask what it is that makes the Way between two distant Bodies easy, the Passage ready and quick? Is it because the intermediate *Space* is prepared for receiving them within it? Why then does the contrary happen, that we can hardly thrust any middle Body between two contiguous ones, nay we cannot do it at all, without impressing a Motion upon it sufficiently strong for separating and removing them from one another? Is it not because there is wanting an Interstice capable of a middle Body? Suppose *ex. gr.* the Body C to reside between the two Bodies A and B, and let the Body C be understood to be removed, so as no other can be permitted to succeed it (the Propension of the neighbouring Bodies to Motion being taken away, or the Effect a little while restrained by a superiour Power); then according to our Adversaries, there will immediately result the most close Contiguity of the Bodies A and B, without the Application of any Force, or Intervention of any Action; they will embrace one another of their own Accord, and presently no Distance will be left between them; and consequently it will be rendered very difficult for the Body C by a contrary Impetus to restore itself into its former Place,

or

or come again between the Bodies A and B, except these Bodies be separated with a strong Force. But it can scarce be understood, why so much Force is required for so small a Separation of Things contiguous, more than for moving together Things separated at any Distance ; why they should meet together of their own accord, and be put asunder difficultly. What should be the Cause why they lost their former State with no Labour, with no Motion, and are scarce restored to the same with a vehement Force and much Motion? Since, as the Way is the same from *Thebes* to *Athens*, and from *Athens* back again to *Thebes*, so the Force is the same, and the Motion equal, for conjoining Things that are distant, and disjoining Things that are together. Moreover, it is somewhat obscure why, according to the contrary Sentiment, in the same Instant wherein the middle Body slides away, the adjacent Matter should not immediately touch one another, and the Intervention not be shut up to the succeeding Matter ; because scarce a Motion that is infinitely swift, much less a slow and Snail-like Motion (such as are often to be found in Nature) does seem to suffice for preventing that Congress ; since it requires no Action here, and instantly emerges by the mere Rebounding. But if the terminating Bodies do easier or sooner close together than Part of the intervening Matter can overtake the preceding, then every Flux must be obstructed, and Motion stopped and taken away ; the Disagreement of which with continual Experience is unknown to none. But are not these Things more simply and evidently dispatched by saying that a Passage is more difficult to be broke through the Joinings of adjacent Bodies, because an Interval is wanting for the Reception of the intervening Body ; but the Transit is easy between the Bounds
of

of Bodies somewhat distant, because a middle Field lies open, which is penetrable and capable of the Entrance of so great a Body ; and consequently if a Vessel be emptied the Sides will not fall together, nor break in Pieces if filled again (since the former seems impossible, and the latter not necessary) but they will invariably retain the same Position, the same Distance, and the same Capacity.

I pass by the Reasons and physical Experiments which are brought for an empty Space (whether entirely filled or interspersed with Bodies), both because I have already spent too much Time upon these Things, whose Examination would still require much Labour, and because most of them may be solved, or at least eluded by those neatly contrived Hypotheses of *subtle Matter, circular Motion, and indefinite Divisibility.*

Thus for the most part is the Matter disputed on both Sides ; what then shall we finally determine? How shall we reconcile these contrary Probabilities, and decline the Difficulties that on every Side beset us ? I on my own Part will advance nothing for true in a Case so nice and dubious, nor assert any thing confidently ; but if I should be necessitated to give my Opinion, and compelled to declare what to me seems most to resemble the Truth, I would not be too averse to the common Conceptions of Men, nor oppose the sacred Laws of Geometry. I would say *first*, that *Space* is a thing really distinct from Magnitude ; *i. e.* that something is designed by that Name, that a Conception answers it, that it is founded in the Nature of Things, that it is different from the Conception of Magnitude, and though Magnitude had no Existence at all, yet there would be Space. I would say, *secondly*, that Space is not
any

any thing actually existent, and actually different from Quantity, much less that it has any Dimensions proper to itself, and actually separate from the Dimensions of Magnitude. You will perhaps say, What will it be then? What means this Riddle? I do not very much promise myself, nor dare hope that I shall satisfy you with mine Answer, but because Form requires it, I reply, that *Space* is nothing else but the *mere Power, Capacity, Possibility*, or (begging pardon for the Expressions) *Interponibility of Magnitude*. I thus explain my Meaning: Before the Creation of the World, there was no Body any where (as is reasonable and pious to believe) but yet it was possible for the greatest Body whatsoever then to exist, and obtain a determinate Position by the Will and Power of God, *i. e. there is Space*. There lies no Body, there is found no actual Dimension beyond the Mass of the Universe; but it is possible for a Body to be constituted and a real Dimension to be extended beyond that itself, *i. e. there is an Ultramundane Space*. If all the Matter be excluded by the divine Power from between these Walls, there will actually be no Body between them, but there will remain a Capacity of putting some Body between them, *i. e. there is an intermediate Space*. Lastly, no Magnitude can be interposed between two adjacent or contiguous Magnitudes; *i. e. no Space or Interval is between them*. A Rope of ten Feet may be extended between those Towers, *i. e. the Space or Distance of ten Feet is between them*.

Here it may be observed by the Way, that the Nature of every particular *Space* is in some sort *determinate*, and in some sort *indefinite*; *Determinate* as to the Mathematical Species and Quantity of its Figure; for it is not every Capacity whatsoever, but only the Capacity of a similar and equal Magnitude; *Indefinite* as to its other Qualities and
 physical

physical Species, also as to the Individuities of the Magnitudes, if I may so speak, for it is the Capacity of every Magnitude equally great and endowed with a similar Figure; *ex. gr.* the Space of a Cubical Vessel between the Sides is computed by receiving any Cube equally great, whether it be of Water or Air, but it cannot be adequately filled with a pyramidal or spherical Body, nor will admit a greater Cube. Hence every positive Interval endowed with actual Dimension and really extended of itself, divisible, terminated, pertransfible, or congruous to Bodies, is not denoted by the Word *Space*; but it only signifies that a Body may be so extended, may be so figured, is adaptable to such a Measure, and may exist either together in the same Instant or successively by Motion. I say it has no actual but only potential Figures, Dimensions and Parts consentaneous to its Nature; by which Means the Capacity of admitting a Body includes the Capacity of admitting Lines and Superficies, respectively; the Power of interposing a Line of four Feet contains the Powers of interposing a Line of one, two, and three Feet, and all others denominated by a lesser Number. The Power of interposing a potential Circle implies perfect Rotundity. Neither can the Quantity or Quality of *Space* be determined immediately or of itself, but by the Measure or Determination of some real Magnitude occupying it; as, *ex. gr.* the Quantity of the *Space* between two Cities can be no otherwise known, than by measuring the Length of a Line stretched upon the Earth or passing through the Air.

This Name therefore of *Space* is not of a mere Nothing or Thing feigned at pleasure, as of an *Hircocervus* or *Chimera*, but is deservedly to be placed in the same Order of Beings with *Creatibility*, *Sensibility*, *Mobility*, and such Possibilities; and there are scarce any but who adjudge some

fort of Reality to these. Nor do I see why this *Space* may not be a Being as well as *Contiguity*, to which it seems to be directly opposed. For *Contiguity* is the Mode of Magnitudes which signifies that no Magnitude can come between them but by moving them out of their Places: And on the contrary *Space* is that Mode of the same which intimates that some other Magnitude may be interposed without moving them out of their Place.

And this Notion of *Space* being supposed and granted, we may untie the Knots and remove the Difficulties of both the aforesaid Opinions. For first nothing can be gathered hence derogatory to the Prerogatives of the Divine Perfection, by supposing a Being really eternal and infinite, unproduced and independent upon God; but rather his unlimited Power of producing and disposing Bodies at his Pleasure is asserted. Neither does the Idea of such a *Space* coincide with the Idea of Magnitude; but differs as far from it, as Power does from Act. Nor does it bring any other new real Beings into the Account besides Substance and Accident, but only denotes some Mode or Possibility of both. Nor will this *Space* require another Place; because it exists no where in an actual Manner, but will however be every where after its own Manner; because God can place Magnitudes any where. Nor is this contrary to the common Sense and Speech of Mankind, who, when they think or pronounce *Space* to intercede, do understand nothing but that some Body may be interposed between assigned Limits. Nor can any Infinity of Matter be deduced hence, but such Extension will follow as God shall please to assign it. Neither does this at all derogate from the Divine *Ubiquity*, which only signifies that God is present to all *Space*, or that something may exist every where. It also conspires and agrees with Geo-

metry most precisely : for neither does this require that some actually real *Mean* shall always intercede between two *Points*, or any two *Terms*; but that sometimes, and in some Cases, a *Line*, *Surface* or *Body* may intercede. It in like manner satisfies the Experiments and Phænomena of Natural Philosophers, affording them as much *Vacuum* as suffices for receiving Bodies, and performing their Motions; nor yet mingling any fictitious *Vacuum* endowed with real actual Dimensions such as *Epicurus* with his Followers dreamed to be one half of the Universe, and the first Principle of Bodies. Again it appears hence that *Space* is immoveable and cannot be carried about with Bodies; because when one Body loses its other Confines or Interstices, yet this Possibility remains, and nothing hinders, but other Bodies equally near and intermediate may be substituted and succeed.

I observe by the Way that this Notion of *Space* seems to be almost direct contrary to the Definition of it which is delivered by (k) Mr. *Hobbes*. He defines *Space* to be the *Phantasm* of a *Thing existing, as existing*. But if *Space* be a *Phantasm* (as indeed it is not, but the Object of a *Phantasm*, something imaginable, and not the Effect of Imagination) it will rather be the *Phantasm* of a *Thing as possible*, than as existing. For when we conceive *Space* we conceive that some Magnitude may exist, though not always that it actually does exist; as before the Creation of the World, or without the present World, according to what was said above. Which does also more agree with his own foregoing Reasonings, than the proper Definition of it which he gathers from thence. For if all Things were conceived to be destroyed, he affirms the *Phantasm* of *Space* would remain in the Mind; but to feign all Things taken

(i) Cap. VII. de Corp.

out of the Way, and at the same Time to imagine the same Things as existing are direct Contradictions. It follows then that *Space* is rather the Idea of Things as possible. But, he says, *No Body affirms that there is Space, for that Reason because it is occupied, but because it can be occupied*: Where he differs not from the Truth, but from himself: For *Space* by Occupation ceases in some sort to be *Space*, as far as Power is extinguished by Act, and a Thing ceases to be farther possible which already exists: Nor is it improperly spoke by the Vulgar, *that Nothing can be poured into a full Vessel, but the Want of Space*.

But I know not what bewitching *Siren* has drawn me upon her Rocks, and held me entangled in her Nets, while I am doing what in me lies to avoid them. This out of the way Philosophy has put a stop to my Course, while I am sailing with all my Speed to the principal Port of the Mathematics. That I may therefore finish this Digression concerning *Space* (indeed too prolix and spacious), and circumscribe it as a Figure within Bounds, I will only remark one Thing more conducing to my Purpose; *viz.* that whatsoever natural Philosophers do determine, this Method of conceiving *Space*, which I have been describing, is most agreeable, and abundantly sufficient for Geometricians: If any Thing more can be discovered in it, or attributed to it, it will no where make against them; but they require no more than to have such an Interval granted, whereby the Figures of Magnitudes and their Properties may continue safe, that they may not be confounded or perverted by a possible Annihilation or Remotion. *Ex. gr.* If two Circles or two Spheres do touch one another, and any two Points without the Contact be taken, as above, in the Circumference of a Circle, or the Superfice of a Sphere, then

Geometry

Geometry requires not that any real or actual Right Line should lie between these two Points, but only a certain potential one ; *i. e.* it requires that a Right Line is possible to be drawn or interposed, or that these Points touch not one another ; since if such Interstice be taken away, or if these Points be supposed to touch, then the Nature of Circles and Spheres with their Properties is entirely destroyed. Such a *Space* therefore ought to be indulged Geometricians for the Foundation of their Hypotheses, and the more, because the *Congruity, Commensuration, Determinate Position, Motion,* and the very *Proportion* itself of Magnitudes agrees with it, and may be explained by it. For *Congruence* is fitly described by a Possession of the same *Space, Mensuration* by a congruous Application or Succession ; a *Determinate Situation and Motion* by the Identity and Alteration of *Space* ; and how *Proportion* depends upon, adheres to, and is illustrated by these, will perhaps hereafter appear.

To accommodate these Things to our Purpose, a Mathematician may frame such Hypotheses as these from what has been advanced. *That this or that Space may be filled, i. e. that Lines, Superficies or Bodies may be interposed between any assigned Points, Superficies or Bodies respectively, which, by Reason of some Property of their Nature, or precedaneous Supposition, do not touch one another.* And on the contrary, *That every Magnitude fills Space, i. e. that a Magnitude cannot be placed between two Magnitudes, but the adjacent Magnitudes on either Side are separate and at a Distance, according to the Manner of the Magnitude supposed. That no Space is tied to any particular Magnitude, but may be successively filled, as the Thing will suffer, by innumerable others, according to its Measure and the Exigence of the adjacent Magnitudes ;* for, as before was explained, *Space* is not a particular, but a

kind of general and indefinite Capacity : And reciprocally. *That no Magnitude is tied to any particular Space.* And which may be looked upon as a consequent Axiom from the foregoing Hypotheses, *That more Magnitudes than one taken together cannot adequately fill the same Space :* For more Acts than one do also argue more Powers than one, or one Act does perfectly fill up and exhaust only one Power ; therefore more Magnitudes than one require more Spaces than one, or one Magnitude takes up the whole constitutive Capacity of only one Space: As the Existence of *Peter* fills and as it were fatiates the whole Possibility of *Peter*, and causes that no other *Peter* can exist the same in Number. And by what Reason any Plurality of Magnitudes do occupy one *Space*, by the same Reason may as many other Magnitudes as you please occupy that same *Space* ; from whence the whole Infinity of possible Magnitude may be contained in the *Space* of one Grain of Barley ; which seems to be inconsistent and contradictory to sound Reason. Also because Magnitudes may obtain the same *Space*, they will also possess the same Termination and Extension and other conjunct Affections of Magnitude, and consequently will become entirely the same ; for we scarce do, or, I believe, can conceive any Thing which constitutes or distinguishes Magnitude except these Affections.

What this last Supposition or (as some chuse to call it) Axiom pronounces or signifies, is wont to be expressed by the Word *Impenetrability*, which many make the primary of all the Attributes of Magnitude, but how deservedly let them see themselves ; for I am for no *Preference of Affections*, but do esteem all reciprocal and equal, as to *Degree*. Only it will be of use to us to take Notice, that this Position is very necessary to Mathematicians,

cians, and, as we have seen, is drawn from sound Reason, and is agreeable to perpetual Experience. For whatsoever in Mechanics is deduced from the *Pulsation*, or *pulsive Force*, of Bodies depends upon this; Also whatsoever in Geometry arises from the *Dependence of Motions* (of which kind is that most elegant Description of Curve Lines invented by *Cartesius* in his Geometry, which is performed by the Impulse or Trusion of Rules in a certain ordinate Reason); because if a Plurality of Magnitudes taken together can fill the same Space, or which is all one, can one penetrate another, then one would not necessarily give way to another, from whence the Supposition of Pulsation would be in vain, and no Effect would result, at least from a scientific Necessity. Therefore the *Impenetrability* of Magnitude is necessarily supposed by Mathematicians, and consequently it was not foreign to the Purpose to shew its Agreement with Reason, and that it is not supposed unlawfully.

By equal Right it may on the contrary be supposed, that no particular Magnitude can occupy more Spaces than one taken together. For one Act cannot satisfy a Plurality of Powers; nor can the Possibility that *Peter* and *Socrates* may exist, be filled with the Existence of *Peter alone*. And by what Reason one particular Magnitude can possess more *Spaces* than one, by the same Reason may it suffice to possess as many *Spaces* as you please: and a Grain of Poppy, or the Magnitude of the minutest Grain of Sand, may be capable to fill all Space and be coextended with the whole Infinity of possible Magnitude, which no Body in his right Mind can be easily led to think.

I must not omit taking Notice, that the same Magnitude by occupying a Plurality of *Spaces* will obtain a Plurality of Extensions, Terminations,

and all other Affections of Magnitude; from whence it will not continue one Magnitude, but become many. Neither is this Supposition unprofitable, but very necessary to Mathematicians: and whatsoever is supposed or demonstrated by them concerning Determinate Position depends on this. For how *ex. gr.* is a Point not in vain supposed or shewn to exist within or without a Circle, if it can exist both within and without at the same Time? How can that Line be said to make such or so great an Angle with this, if it can constitute any other Angle at the same Time while it obtains a different Position? How can a Right Line be demonstrated to touch a Curve from hence, because the Whole falls without the Curve saving the Point of Contact, when it is repugnant for it at the same Time to lie altogether within it? How lastly can a Point be proved not to be the Center of a proposed Circle from hence, because it does not bisect the Diameter, if, by reason of the various possible Situations, the same Point can bisect the Diameter and not bisect it at the same Time? Whatsoever then may be said of the Popish Divinity, except the Hypothesis be true, that it is not possible for the same Magnitude to fill more Spaces than one at the same Time, there is an entire End of all Geometry. But we cannot now add every thing worthy of Observation concerning *Determinate Position*; no more than concerning the other remaining Affections of Magnitudes which are to be reserved for the following Lectures.

I will only add this one Observation more, that there is a great Affinity and Analogy between *Space* and *Time*. For as *Space* is to *Magnitude*, so does *Time* seem to be to *Motion*; so that *Time* is in some sort the *Space* of *Motion*. For when *Time* is called a *Year*, a *Month*, or a *Day*, nothing seems

seems to be signified but that such or so great a *Motion* is performed, or intercedes, or may be interposed in the mean while ; *ex. gr.* one Period of the *Sun* in the *Ecliptic* ; one Return of the *Moon* to the *Sun* ; or one *Revolution* of the *Heavens* (or the *Earth*) about its *Axis*. But this by the by, for *Time* itself now forbids us to treat more fully concerning *Time*.

LECTURE XI.

Of the Congruity and Equality of Magnitudes.

IN the foregoing Lecture we have spoke sufficiently concerning the Nature of *Space* and certain Mathematical Hypotheses which are drawn from thence. The next Affection of Magnitude, which offers its self, is *Congruity* ; the Supposition of which is as it were the chief Pillar and principal Bulwark of all the Mathematics. For from hence, in my Opinion, is taken the formal Reason of *Equality*, which is all in all in the Mathematics ; and, as (*k*) *Proclus* says, *the most original Affection in Quantity* : at least it is in fact the most principal Criterion, and affords the leading Argument of the same ; as it will be perhaps worth while to shew.

The *fourth Proposition* of the *first Book* of the *Elements* (which by *Proclus* is not undeservedly called the most simple and evident in Speculation) demonstrates the *Equality* in all respects, of two Triangles having two Legs equal and the Angles contained between those two Legs also equal, from

(i) Ad. 4. I.

the

the *Congruity* of the Sides and Angles ; only assuming the Axiom, *That two Right Lines comprehend not Space*, or which comes to the same, *That two Right Lines having the same Terms are congruous*. From this is demonstrated the *Equality of Triangles and Parallelograms* constituted upon the same Basis, and between the same Parallels, only applying the Axiom, which is also demonstrable by *Congruity*, (as shall be hereafter shewn) *If equal Quantities be added to Equals, the Wholes ; or if equal Quantities be subtracted from equals, the Remainders shall be equal to one another*. From thence by the Axiom ; *that Things equal to the same third are equal to one another* (which Axiom may in like manner be demonstrated by *Congruity*) the same is demonstrated concerning *Parallelograms and Triangles* constituted upon equal Bases. From these, applying also the Definition of *Proportionals*, is deduced the *Proportionality of Parallelograms and Triangles* of equal Heights, with their Bases, or of equal Bases, with their Heights. Hence the *Similitude of equiangular Triangles* ; then, in equal *Triangles and Parallelograms* having one Angle equal, the reciprocal Proportion of the Sides about the like Angles ; and interchangeably the Equality of the Sides of the Figures are derived from the reciprocal Proportion of their Sides ; and all the other principal Affections of plane Figures, which are especially contained in the *sixth Book of the Elements*.

Also otherwise, without applying the *fourth Proposition* of the *first Book of the Elements*, these abovementioned *Equalities and Proportionalities* of *Triangles and Parallelograms* are deduced by that excellent *Method of Indivisibles*, the most fruitful Mother of new Inventions in Geometry, which was not long ago published and applied to common Use by *Cavallerius*. The Foundation of which most elegant and useful Method (as its
Author

Author does not obscurely intimate) is from *Congruity*, and is demonstrated by *Congruity*, as will appear to any one who does but attentively consider the first Propositions of his second Book concerning the Geometry of *Indivisibles*, or some few of the first Propositions of the same Author's first Exercitation.

In like manner the *eighth Proposition* of the *first Book* of the *Elements* about the *Equality* of Angles subtended by equal Sides, in Triangles, whose Legs are equal (which is another plentiful Fountain of Geometrical Theorems, especially abounding with such as respect the Affections of Circles) is there demonstrated, and can be no otherwise demonstrated, than by this *Congruity*, either immediately, or mediately.

I pass by many other particular Demonstrations depending upon the Supposition of this, which are extant in *Archimedes*, *Pappus*, and many other famous Geometricians. From whence the most sagacious *Willebrord Snellius* calls *Congruity*, the most elegant Utensil that belongs to the Furniture of Geometry. They therefore who despise and reject it in mathematical Demonstrations, as favouring too much of mechanical Bungling, do endeavour to overthrow the very Basis of Geometry; but without either Wisdom or Success. For Geometricians do not perform their *Congruity* by the Hand but the Thought, not by the Sense of the Eye but the Judgment of the Mind. They suppose an accurate and perfect *Congruence*, which no Hand can perform, nor any Sense discern, and from that Supposition draw just and logical Consequences. Here is no need of Rule or Compasses, no Labour of the Hands, but the Whole is the Work, the Artifice, and Device of the

(1) Snell. Praef. ad Cyclometr.

Reason; nothing is required which favours of Mechanism, but only as far as every Magnitude is involved in some Sort of Matter, is exposed to the Senses, or is visible and palpable; so that what the Mind demands to be understood, the Hand can execute in Part, and the Praxis can in some measure emulate the Theory. Which Imitation notwithstanding, is so far from weakening or depressing the Strength and Dignity of *Geometrical Demonstration*, that it affords it a much more strong Confirmation and an higher Advancement; by sensibly proving the Reality and Possibility of the assumed Supposition, which indeed (as we have often insinuated) is the genuine Foundation of all Science; and thus establishing the Authority of Reason by the Suffrage of Experience. Consequently they, who asperse the Knowledge of Mechanics in those Demonstrations where *Congruity* is applied, do rather accuse them of the greatest Perfection, than of any Defect or Blemish, and in Reality do the same as to reproach them for their excellent Familiarity and Facility, for their too great Evidence and Nobleness. Nor indeed has *Ramus* himself any Thing here to find Fault with, though one that has no great Favour or Good-Will towards the Ancients, but willingly gives his Vote, and very much approves, commends, and uses the Method of Reasoning, which is drawn from *Congruity*. *This Kind* (says (m) he) *of Euclidean Demonstration, so expedite and facile I do very willingly embrace.*

But why do I go about to defend the Method of Demonstration, which is commonly received and used by the very Princes and Ring-leaders of Geometry (viz. *Euclid, Archimedes, Apollonius, Pappus*, and others) against such pitiful

(m) Schol. Matt. Lib. VIII. 170.

Smatterers?

Smatterers? Rather let us consider the Nature and Quality of this Mathematical Congruity a little nearer. *Congruity* is wont to be described by the *Occupation, Possession, or Repletion* of the same *Place* or *Space*: which may be conceived to be done three ways, *viz.* by *Application, Succession, or Mental Penetration*. (1) By *Application*, when one Magnitude is conceived to be so laid upon, or applied to another, as immediately to touch that other with all its Parts, and no where recede, or be separated from it: As when a Measure is applied to, and coextended with the Thing measured (as a Yard-Wand to the Selvage of a Web; or assigned Right Lines to the Surface of the Earth) in which *Application* all the Parts of one Longitude do exactly answer to and immediately touch the Parts of the other, and consequently these are congruous to one another after this manner. (2) By *Succession*, when one Magnitude is conceived to enter the Place of another Magnitude removed; as when Water is poured out of a Vessel and Wine poured in, these Magnitudes are said to be congruous by reason of the *Identity of Space* which they successively occupy. (3) By *Mental Penetration*, when we conceive the Magnitudes of two Bodies to grow together, coincide, and as it were unite into one by the Possession of the same Place in the same Time: By which *Congruity* nearly the Writers of Perspective do suppose a Table interposed between the Eye and a radiant Object, every where perspicuous, and as it were penetrated with the lucid Cone or Pyramid so as no where to hinder the Rays from passing through, but to receive them all upon it, and retain their *Vestigia* as impressed upon or united into it.

Of these Ways of *Congruity*, that which is performed by real *Application* agrees with *Lines* and
Superfices

Superficies only, which by reason of their Indivisibility may touch the Whole of one another immediately, and by this Contact, as it were penetrate one another and coincide in one. Whence Geometricians do account such congruous *Lines* and *Superficies* as one : Which seems to have been meant by *Euclid*, when he denies *Space* to be comprehended between two Right Lines, as also a solid Space between two Planes. The Points which terminate a Plurality of contiguous Lines, they always account for one common Point ; as also the extreme Lines which determine a Plurality of conjunct Superficies they take for one Line ; and lastly the Superficies which terminate Bodies they suppose to coalesce into one Superfice. And this is reckoned as a Postulate by *Vitellius*, viz. *that when two plane Superficies do touch one another, they become one Superfice.* And by the same Reason, the concave Circumference of a Circle coincides with the convex Circumference of another included concentric Circle, which is perfectly contiguous to the former : Also the concave Superfice of a Sphere coincides with the convex Superfice of another included concentric Sphere, which is perfectly contiguous, as before.

But Bodies by reason of their internal Thickness have only their external Superficies contiguous, and consequently no Part of them can be congruous by *Application*. Wherefore some of the Moderns do utterly deny them to have any *Congruity* at all. But at least the *Congruity* performed by *Succession* (viz. by Means of a common Space) pertains, and is extended to all Magnitudes universally : Since no Magnitude is peculiarly tied to any one *Space*, nor, on the contrary, any *Space* to one Magnitude, but the Place left by one may be occupied by any other equal and similar Magnitude.

Lastly,

Lastly, The *Mental Congruity* of Magnitudes is not absurdly supposed to be also of Solids, whatsoever the above named Philosopher may think. For *first*, no *actual* or *real Penetration* is asserted by it, but only it is abstracted in the Mind; neither does the *exclusive Force* of Bodies, which hinders *real Penetration*, come into Consideration; but the general and indefinite Capacity of admitting an equal Body is only considered separately by itself, which is the principal Property of Space. Which Manner of Conception the Philosopher does often absolve from Falsity. *Neither*, says (b) he, *when they abstract, does it become false.* *Secondly*, This *mental Penetration* is no otherwise supposed by Mathematicians, than as *real Penetrability* is destroyed by it, and demonstrated to be absurd. For because it is supposed that two Bodies fill the same Place, they demonstrate from thence, that the Magnitude of both is the same, and therefore that by *penetrating* one another they cease to be two; and consequently that two Bodies (*i. e.* formally two Bodies) cannot *penetrate* one another. It is lawful to suppose any Thing however false and absurd, that such Falshood and Absurdity may be the better understood. Nor can scarce any negative Proposition be convinced of Falshood, any other Way than by detecting the Falsities that follow from the Supposition of its Truth. Thus therefore do Mathematicians apply this *Penetration*, which is supposed in the Mind, as those apply it, who endeavour to demonstrate the *Impenetrability* of Magnitude itself from the Supposition of *Penetration*. For Mathematicians only use it for discovering or proving the *Equality* or *Inequality* of Magnitudes, by which Means I affirm that two Spheres

(n) *Phyf. II. 2.*

described with equal Diameters are equal ; for the Center of the one may be conceived to be congruous with the Center of the other ; whence, by reason of the *Equality* of all the *Radii*, the external Superfice of the one will not exceed the external Superfice of the other, therefore the Whole of the two Spheres will be congruous, therefore they will have the same Magnitude, *i. e.* they will be equal. But if the Diameter of the one be supposed greater than the Diameter of the other, if the Centers be conceived congruous, the ambient Superfice of one will exceed that of the other, because, by reason of the supposed unequal *Radii*, it is farther distant from the common Center ; therefore the Magnitude of both will not be the same, *i. e.* they will therefore be unequal.

But if any one do nevertheless oppose this *fictitious Penetration*, as not sufficiently satisfactory ; I add, that this mental Congruity may be conceived by Succession, *viz.* by conceiving the one to vanish, and the other to be substituted in its Place, *i. e.* to be interposed within the same Term, or contained within the same Ambit ; by which Means there will be no Difficulty, but this *Penetration* may be conceived almost the same Way, whereby a Sphere revolved about its Axis does penetrate itself ; as one Part does perpetually succeed in the Place of another. Whence it appears that *Congruity* is nothing else but *the Occupation or Completion of the same Space or Place*, whether in the same Time or successively, from which there results a sort of Identity of Magnitudes, or Coalition into one. For indivisible Magnitudes because applied to one another, (according to their Indivisibility) do fill the same Space in the same Time, and as it were coincide together ; but solid Magnitudes every Way really divisible are conceived

ceived to be in the same Space, either at different Times by *Succession*, or at the same Time by *mental Penetration*, and are united and identified between themselves by the Intervention of that Space, as far as their Quantity is united and identified with it. But that this Affection may be yet more apparent, I observe moreover that *Congruity* (especially that which is conceived by *Apposition*) may be understood to be handled various Ways, and as it were by certain Degrees:

First, So, that the whole Magnitudes taken together do possess the same Space in the same Time, the Situation of the Parts being no where varied: By this may be congruent all Right Lines, plane Superficies, Peripheries of equal Circles, Superficies of equal Spheres, similar Spirals in equal Circles, Cylinders, or Spheres; and all other Magnitudes whatsoever, which are similar and equal. This is the highest Degree of most *perfect Congruity*.

Secondly, So, that they coincide with the same Space successively by Parts, the Situation of the Parts again being no where changed. By this Way may be adapted the Perimeter of every Right lined Figure to a Right Line extended at Length, and the Surface of a Prism to a Plane Superficie stretched upon a Level. Which is the next Degree of *possible Congruence*.

Thirdly, So, that all the Indivisibles of each Magnitude may succeed in the same Place, and neither of the two vary the Position of their Parts. By this Method while a Wheel or a Circle runs forwards upon a Right Line always contiguous to it, and in the same Time is turned about its Center, its Periphery is congruous to the said Right Line; because all the Points of the circular Periphery are continually applied in a successive Order to all the Points of the Right Line. There-

fore, to observe this by the by, it is manifestly perceived from *Congruity*, that a Right Line may be made equal to the Periphery of a Circle, and consequently the Quadrature of a Circle is not a Thing altogether impossible in its Nature, which is thus expressed by the above-mentioned most acute (i) Geometrician in his *Cyclometria*: *Such is the Mechanical Revolution of every Circle till it return to the same Point of the Periphery, where the Circumduction was begun; which indeed argues, and as it were lays before the Eyes, that a Right Line may be really exhibited equal to the Perimeter of a Circle.* And by like Reason a Cylinder turned about its Axis proceeds upon a plane Superfice, and its curved Superfice is exactly equal to the said plane Superfice: Because all the parallel Right Lines, which lie disposed one after another in the Superfice of the Cylinder, are applied, by a continued uninterrupted Series, to all the parallel Right Lines in the plane Superfice.

Fourthly, So, that all the Indivisibles of both Magnitudes do occupy the same Place in the same Time, the Situation of the Parts of one being in some measure unvaried, but yet their Order preserved, and the former Contiguity of the particular Parts retained. By this Way the Periphery of a Circle, or any other Curve, may be so stretched or extended as to pass into a Right Line, and consequently be congruent with a Right Line; and on the contrary a Right Line may be so incurvated, as to degenerate into the Periphery of a Circle, or any other Curve Line. And the same Way may any curve Superfice be extended into a plane one, and reciprocally any plane Superfice into a curve one. And indeed (to explain the Matter a little farther) it may be often plainly

(o) *Snellius.*

enough

enough discerned how curve Lines may be made out of, and resolved into Right Lines, also from what plane Superficies may arise curve ones; which may be stiled the *Involution* or *Evolution* of *curve Lines* and *curve Superficies*. *Ex. gr.* as to curve Superficies, the curve Superfice of a Cylinder is nothing but a Right angled Parallelogram, having its Basis equal to the Periphery of a Circle, which is the Basis of the Cylinder, and of the same Height with the Cylinder, all whose Right Lines parallel to the Basis are bent or incurvated into the Peripheries of Circles; from whence the cylindrical Superfice is congruous with this Parallelogram, if any side of the Cylinder (*i. e.* any Right Line drawn from Basis to Basis upon its Superfice) be applied to the Side of the Parallelogram, and thence the whole Superfice expanded into a Plane; or if by the Application of the Side of the Parallelogram to any Side of the Cylinder, its Plane be rolled about the Cylinder, and as it were do clothe and cover it on every Side. In like manner a conical Superfice is only the plane Sector of a Circle having its Radius equal to the Side of the Cone, and its Arch equal to the Periphery of a Circle which is the Basis of the Cone, and whose concentric Arches are incurvated into as many perfect circular Peripheries: Or rather otherwise, a Conical Superfice is only a Right, angled Triangle, whose Altitude, or Perpendicular, is equal to the Side of the Cone, its Basis to the Periphery of a Circle which is the Basis of the Cone, and all whose Right Lines parallel to the Basis are bent into so many circular Peripheries. So also the curve Superfice of a Sphere (with every Superfice of a plane Figure which is generated by a like Rotation) may be easily reduced to a trilineal Plane comprehended within two Right Lines constituting a Right Angle, and

a curve lined subtense. But how that is done, it does not belong to this Place to explain. But as to Curve Lines, besides the Circumference of a Circle (which is nothing but a Right Line every where similarly and uniformly bended through all its Parts) I say, besides this, the cylindrical Spiral (which is the most simple, uniform and similar, as to its Parts, of all other Curves) is nothing but a Right Line equal to the Diagonal of the aforesaid Parallelogram (to which the cylindrical Superfice is reduced) it being circumvolved about the cylindrical Superfice. Concerning the Reduction of other Curves to Right Lines, or to other kind of Curves, I am at this Time silent, lest I should be both too prolix, and at the same time too obscure in a Thing only handled by the by. To this Mode also belongs, or is very near of kin to it, that *Congruity* of which equal Figures included within the same parallel Lines or Planes are capable; of which all the Lines or Planes intercepted between the same Parallels are equal. As two Triangles or Parallelograms not equiangular to one another, or two Pyramids, Prisms, Cones, Cylinders unequally inclined, constituted between the same parallel Right Lines or the same parallel Planes, and upon equal Bases. For as one of these is congruous to another, the Situation of the Parts of one ought to be accommodated to the Position of the Parts of the other, yet without disturbing their Order, or losing their former Contiguity.

The *fifth* Way is, when the *Congruity* may be so performed, that the Position and Order of certain Parts is changed. This Way of Congruity of all the most imperfect and difficult to be understood, agrees with homogeneous Figures altogether unlike to one another. *Ex. gr.* A Triangle is no otherwise congruent with a Circle, a Cone with

with a Sphere, than by transposing the Parts of either, by applying a Part of one to a Part of the other, and a part of the Residue in one to a part of the Remnant in the other; and so perpetually, till the Business be finished, and all the Parts of the one be at length applied to all the Parts of the other; which Thing whoever desires to have distinctly explained I advise him to go to the above mentioned Places of *Cavellerius*.

From these Things it will appear to him who more attentively considers that all Magnitudes of the same Kind may be some way made congruent to one another, *i. e.* Lines to Lines, Superficies to Superficies, and Solids to Solids, either the Wholes at the same Time, or by their Parts (or Indivisibles) successively, the Situation of the Parts being retained, or taken something at large, or at least transposing them: I say all Magnitudes may be congruous by taking *Congruity* at large, for any Coincidence though inadequate; by which means a lesser Right Line laid upon a greater Right Line will be congruous to it, *i. e.* will coincide with it wholly, though not with the Whole of it.

But *Congruity* more strictly taken, is only attributed to equal Magnitudes, which neither any where exceeding, nor falling short of, its Bounds, do precisely occupy the same Place, *i. e.* do justly fill it, and are contained by it. And indeed some do place the *formal Reason* of *Equality* itself, in the *Aptitude* or *Power* of such *Congruity* with which Magnitudes are oftentimes endowed, and from thence define it, in my Opinion, not badly. Of the Ancients the great *Apollonius* was of the same Mind, as appears from his Demonstration of that celebrated Axiom of *the Equality of Things equal to the same third*, which *Proclus* produces and impugns. Which Demonstration depends upon this Definition of *Equality*. *Those Things are equal to one another*
 O 3 *which*

which possess the same Place. And lately our Countryman Mr. Hobbs has also defined equal Bodies to be such as can occupy the same Place. But a Body (says he) may occupy the same Place, which another Body occupies, though it be not of the same Figure, if it can only be understood to be reduced into the same Figure by the Flexion and Transposition of its Parts. Which Assertions of Hobbs, his great Adversary does largely canvass and very acutely endeavour to refute; but according to my Judgment, not to dissemble the Truth, not with the utmost Efficacy. For I am notwithstanding more of the Opinion of Apollonius, and think that Equality is appositely enough defined from a possible Congruity. I will give some Reasons for my thinking so, and examine this Matter a little more curiously (proceeding gradually), because it seems worth the while, and makes something for our Purpose.

And first, though it may be somewhat questioned, whether it be expedient to assign any Definition of Equality, for (p) Aristotle seems to think it not at all necessary; because the Notion of Equality is perspicuous of itself, and its Signification abundantly plain to every one. To subduēt Equals from Equals, says he, assumes not (i. e. explains not) what Affections do signify, nor does it assume (or explain) what the common Terms (i. e. of Principles or Axioms) signify, because it is manifest. Though I say it may be thus doubted whether Equality ought to be defined at all, nevertheless I think it for the Benefit of the Mathematics, to have what is understood by it distinctly defined, and explained. For since Equality is an Affection of that Kind that it does not immediately occur to the Sense or Experience, but results from an instituted Comparison of Things, (at least without Compa-

(p) Polit. I. 10.

rison it is not apprehended by us) and since Things may be differently compared with one another, therefore it seems to be required of us to determine from what and what Sort of Comparison, when and after what manner we conceive *Equality* to result, by some certain Argument, undoubted Criterion, or annexed Sign evident, reciprocal, and expressed by a Definition; that we may have a distinct Notion of it, and that no Cause of Doubt or Difference may possibly arise. It is indeed needless for those Things which are more immediately and frequently exposed to the Senses, (of which the first indemonstrable Hypotheses do consist) to be explained in other Words besides their vulgarly received Names, because they impress the same distinct Ideas of themselves upon all Men. For I take no Notice of their Opinion, who think the Species of *Equality*, *Similitude*, and such Relations, to be implanted in us by Nature; since that Device (as we have seen above) is unnecessary and unfuitable for the Sciences; nor does it depend upon any solid Reason, that I can perceive, except certain Metaphysical Perplexities and Niceties of Words. But to cut off all Occasions of Dispute, it seems to be of Use to the Sciences, most accurately to determine all the other secondary Conceptions, which do any how result from the Comparisons of these first Hypotheses one with another, by confining these first Hypotheses from whence they arise. For, strictly speaking, in raising any Science from its first Foundations, it is scarce lawful to apply any Word, which is not before defined, or at least to which we cannot most evidently demonstrate something answering in Nature. Which ought to obtain so much the more in this Affection of Magnitudes, which we are now treating of, because it bears the principal Part, and almost always occurs in every mathematic

equality
 to
 Dispute
 in it
 to be

mathematical Subject and Discourse, and consequently it rightly behoves all Students of those Sciences to have one agreeable and common Idea of it, clear, distinct, and consentaneous to Reason; and that they do not apprehend it confusedly or disagreeably. And indeed, since we ourselves do seek and dispute what this *Equality* is, wherein consists its *formal Reason*, and how it ought to be defined, it may be an Argument that it ought to be defined. To this I add, that the Definition of *Equality* ought to be known and ready, at least because it is incumbent upon me to defend this, *that all Axioms are to be accounted for Theorems*, and may and ought to be demonstrated, (if the Thing require it) and that especially from the Definition of the Terms of which they consist: from whence the Truth of these Axioms may appear concerning the *Equality* of Things equal to the same third, of the Sums or Differences of equal Quantities added or subtracted from Equals, and the like. I add also that through a want of this Definition there would happen, nay perhaps in Fact has happened (to the Disparagement and Detriment of this Science) an Occasion of Quarrels, Animosities and Broils in the calm and peaceable Province of Geometry. For one or two convenient Definitions would perhaps have easily quieted, decided, and taken utterly away the Strifes between *Clavius* and *Peletarius*, and other skilful Geometricians, concerning the *Angle of Contact*, (which were increased by angry Minds and contumelious Words) if the Definitions of *Equality* and *Angle* had but been rightly constituted, and the Ambiguity of these Words taken away. It is therefore expedient to lay down some Definition of *Equality*; let this be holden in the first Place.

Moreover *secondly*, because as I have said often heretofore, and am fully persuaded, that every
Definition

Definition ought to be sought from some possible Supposition depending upon manifest Experience; and since if we attentively weigh and examine whatsoever is of kin to this Business, I believe no Hypothesis will offer itself more accommodate for founding the Definition of *Equality* on, than this of the possible *Congruence* of Magnitudes: therefore this ought by all means to be embraced and acknowledged. That no one more accommodate does offer itself, will evidently appear to any attentive Person by manifest Tokens. For no Hypothesis is more frequently observed, exposed to the Senses, beheld with the Eyes, and touched with the Hands; none is understood more clearly, or supposed more possible. And when the Question is about the *Equality* or *Inequality* of Things, the Contention is always determined by appealing to *Congruity*. Which is a sufficient Sign that this Notion of *Equality* most aptly agrees with the common Conceptions of Men; and that when Men say two Magnitudes are equal, nothing is understood but that by their Application to one another they are congruous between themselves, or at least do fill up the Capacity of the same Space.

And I will yet confirm this by an Experiment very familiar to me. I have often been asked by such as were unaccustomed with Geometry, What that famous Problem meant or did signify about the *Quadrature of the Circle*? The Answer was ready, that it was to find a rectilinear quadrilateral Plane rectangular and equilateral, whose Area or Space included within the linear Perimeter may be most accurately equal to the proposed Circle, *i. e.* to the Plane Area which is circumscribed by the circular Periphery. But they then were wont to insist upon what is meant by this *Equality*. For how, say they, can a round circular Space be equal

equal to an angular Space, when they cannot be congruous and adequate to one another? This Doubt (which sufficiently intimates that most Men do understand nothing by *Equality* but the *Congruity* of Magnitudes itself) will be easily removed, if we suppose the said quadrilateral Figure (as if it consist of Wax, or of any other Matter, soft and perfectly flexible) by the Inflection, Transposition or Compression of certain Parts to be somehow transformed into a circular Figure, and then being applied to the Circle is exactly congruous to it; in which Case, I say, these Figures do become equal, and the *Quadrature* is performed which we sought with so much Study. To this Answer, which is purposely adapted to Men's preconceived Notions, they immediately acquiesce; from whence it is sufficiently apparent that by *Equality* is understood nothing else but a *possible Congruity*.

To this *thirdly* may be added that which seems to me the most conclusive Argument of all, which is as follows: *Equality* is most appositely defined from that Property, upon which all the Theorems about the *Equality* of Magnitudes do depend, from which they are deduced, and to which they are ultimately referred; from whence consequently the remaining Affections of equal Magnitudes, as such, are derived: But all the Things demonstrated about the *Equality* of Magnitudes do depend upon *Congruity*, are either mediately or immediately deduced from it, and demonstrated by it, and lastly are ultimately resolved into it. Therefore *Equality* is most appositely defined by it. The Truth of the major Proposition of this Syllogism is sufficiently clear from the Nature of a Definition, whose Office it is to exhibit some primary Affection, from whence, as from a formal Cause, the remaining Properties of the Thing defined are inferred by a lawful Discursus. Therefore if equal
Magnitudes

Magnitudes be defined to be such as are capable of being precisely congruous to one another, and their Affections of being demonstrated from this expressed Affection of equal Magnitudes as such; it will be sufficiently apparent, that the Definition from thence is lawful. But things are thus, and the Minor is equally true. For in fact whatsoever is demonstrated about the *Equality* of Things in the Elements, and consequently every where else in the Mathematics, depends upon this Axiom, *That the Things which are congruous are equal*, as was shewn in the Beginning of this Lecture, and will perhaps be hereafter shewn more clearly. Consequently they, who receive this Axiom as put for the Definition of *Equality*, seem to do very rightly; to whom (besides the abovementioned *Apollonius* and *Hobbs*, I may add the learned *Borellus*; For, says (q) he, *if no Name were yet imposed for Equality, it might be said that those Things which are mutually congruous may be called Equals, and this would be a Definition, not an Axiom*; therefore he thinks this Axiom to differ no otherwise from the *Definition* of *Equality*, than in the manner of expressing it, and grants that it may be easily changed into a Definition. But I do not entirely agree with this most learned Man's Insinuation, that it becomes rather an Axiom than a Definition, because of the Name of *Equality* being first imposed and vulgarly received. For though the Names of some Kind of Things, *viz.* of a Triangle, or a Circle, be received and commonly used, yet, it is requisite for those Names to be defined, to prevent confused Notions concerning those Things and Words. For the Vulgar distinguish not, but frequently keep the Ideas answering to the accustomed Names very confused

(q) *Eucl. Restit.* p. 16.

and

and inadequate; whereas the Genus and Reason of Sciences require very distinct and adequate Conceptions; and consequently Teachers of Sciences ought to define the most received Names of Things, and clear the Signification of Words from vulgar Confusion; especially of such Things as are not obvious to the Senses and leave not clear Ideas of themselves upon the Mind. Though the Name of *Equality* is no otherwise received than as it designs what is expressed in the said Axiom, *viz. That Magnitudes, which are said to be equal, are congruous* to one another. Therefore that Axiom contains a Definition of *Equality* most agreeable to the Ideas of the Vulgar.

To these Things it may be adjoined *fourthly*, that our Adversaries are able to devise no Notions of *Equality* more fit, nor, by excluding this Notion, can aptly interpret what they mean or distinctly understand by *Equality*. The Antagonist of *Hobbs* reminds him of his two other Descriptions which he thinks to be more apposite than that taken from *Congruity*. He demands of *Hobbs*, Why he could not at the same time, and in the same Words have said, *That is equal to another, which is just as much as itself; or those Things are equal whose Quantity is the same; or if neither of these please, to have invented another Definition?* To which Words it may be answered in the first Place: It is probable, that most acute Man was not able to invent a Definition more accurate than these two which he brings; for if others had occurred it is likely he had not omitted them. But these two do either seem to signify nothing at all, or to result into *Congruity*. I do not indeed dislike, but willingly embrace, that Definition, which seems to be borrowed from (r) *Aristotle*, that those

(r) Met. IV. 16.

*Things are equal, whose Quantity is the same, if by it is denoted not an actual, but a possible Identity of Quantity, as it ought to be understood, lest the Proposition be convinced of manifest Falsity by attributing the same Quantity to equal Things, i. e. to Things actually different. I say, I find no Fault with this Definition so understood; but I ask how the Quantities of two Things can become the same otherwise than by Congruity; i. e. except they coincide or are as it were co-united together some of the above expounded Ways, viz. by Application, Mental Penetration, or the Intervention of some mean Space? For indeed I can hardly see or conceive how the Quantities of two Things which are really distinct from one another can possibly be the same. But as to the other Definition, viz. that is equal to another which is just as much as itself; first I oppose to it that logical Law prescribed by (s) Aristotle with the highest Reason. Since a Definition is delivered for the sake of declaring a Thing, and we do not declare from Things taken unadvisedly, but from such as are prior and more manifest; from hence it appears, that he who defines not from such Things, defines not at all. I say, I object this most just Law against the above-cited Definition; for who does not, with as equal Ease conceive what is equal to another, as what is as much as itself? But perhaps to one who more thoroughly considers it, the Word *as much* will be found to signify nothing else but *as much the same*, or, *whose Quantity is the same*; and consequently this Description, if rightly understood and explained, will differ nothing from the foregoing one, but will the same Way fall in with our Hypothesis of Congruity. Consequently our Adversaries are unwarily forced*

(s) Top. VI. 4:

to establish our Opinion while they are studying to overthrow it; and do sufficiently betray themselves, that in reality they hardly differ at all from us, as they most gladly would.

Lastly, I omit, that *Euclid* is expressly said to have defined *equal Magnitudes* to be *those which fill the same Place* in a Book, which I never saw concerning *Gravity* and *Levity*. My Author is *Ramus*. But a greater Light will accrue to this (t) Cause (greater, I say, to the Nature of both *Congruity* and *Equality*) from a Discussion of those Arguments, which I deny not to be in Appearance sufficiently valid, that are produced on the contrary Part by *Proclus*, and the above-mentioned most learned Man; which I abstain from, for the present, lest I should be too prolix.

L E C T U R E XII.

An Examination of the Objections brought by Proclus, &c.

OF the more common Affections and Properties of Magnitudes, which occur to Observation and introduce Mathematical Hypotheses, the last that offered itself was *Congruity*; from the Supposition of which, we have in Part declared in the preceding Lecture, that the *Equality* of Magnitudes results and is aptly defined by it. Which Doctrine notwithstanding *Proclus* and *Hobbs's* celebrated Antagonist in his Confutation of the *Hobbian* Geometry do strenuously oppose, as they think, with invincible Arguments. It now re-

(t) Schol. Math. VII. p. 163.

mains and is incumbent upon us to weigh the Efficacy of the Things objected in the Balance of Reason, and see whether the War be ended, and they have obtained a Victory as compleat as they imagine. Which we undertake to examine the more readily, because there will arise no small Light to these Things from these Conflicts of contrary Sentiments and Reasonings. Certain Sparks of Truth, by no means to be slighted, seem capable of being struck forth; and yet I will not trouble myself very much with removing every little Cavil, but will more diligently examine the Arguments which by a candid Acceptation do seem to approach nearer the Business, and to contain in them something of more weighty Moment, being mindful of *Aristotle's* Divine Precept, (*u*) *That Things will be more credited if the Arguments on both Sides be first heard. For it does not become us to give Sentence without hearing the Cause, or condemn any Side unheard. They who are willing to judge well of the Truth ought not to be Adversaries, but Arbitrators.* I will therefore, as far as I am able, propose such Arguments from them as are most nervous.

They pretend then *first*, that the same univocal common Reason, and general Notion of *Equality* ought to be assigned for all those Things to which *Equality* is truly attributed and justly agrees. But *Equality* is with the same Reason and like Propriety of Speech wont to be attributed and truly to agree, not only with Magnitudes (*viz.* which have this peculiar *Congruity* we are contending for) but also with all homogeneous Quantities, which are fit to be compared together, (*viz.* Motions, Times, Velocities, Weights, Numbers, &c.) though *Congruity* do by no means square with

(*u*) *De Cælo* I. 10.

them. *Equality*, says *Proclus*, agrees with all *Quantities* in common *Continued* and *Discrete* : And the other Adversary; *Is not the Notion of Equality the same in all these, ay and in all other Things as many as are capable of Equality or Inequality?* (v) Whereby he makes, that, about whatsoever *Equality* they are conversant, the *Axioms* laid down in the *Elements* of *Geometry* both are and lawfully may be accommodated to all *Quantities* indifferently ; from whence they are stiled *common Axioms*. Each of these, says *Proclus* again, is not only truly spoke of *Magnitudes* but of *Numbers*, *Motions*, and *Times*. And *Aristotle* himself speaks to the same Purpose, *It is* (says (x) he, bringing an Example of a common Principle) *common to all Quantities that where equal Things are taken away, the Remainders are equal*. Therefore, say they, the Reason of *Equality* is unadvisedly taken from *Congruity*, because it is proper to *Magnitudes* alone, and agrees not with other *Quantities*, and consequently is no where coextended with *Equality*, but confined within much stricter Bounds. For from the justest Prescript of *Logic*, *the Thing defined ought to be exactly coequal and convertible with the Attribute by which it is defined*.

To this primary Exception, that it may be sufficiently apparent to some who urge us pressing-ly, I answer briefly, in the *first Place*, that the *Equality* of *Magnitudes* only is here properly and principally defined. *Secondly*, that it may be lawfully and rationally defined alone by itself. *Thirdly*, that this Definition (I mean the Definition fetched from *Congruity*) may be fully adapted to all *Quantities* its own Way. *Fourthly* and *Lastly*, that it is necessary, at least lawful, for the sake of greater Perspicuity and Security, that the

(v) *Elench.* p. 10.(x) *Met.* XI. 4.

Equalities of other Quantities be defined separately. By the more distinct Explanation of which Particulars, and the different Approbation of equal Judges of the Business, I imagine the Objection brought will be compleatly answered.

As to the *first* Point, there is no Controversy about it; for our Adversaries deny not that Magnitudes only are especially capable of *Congruity*, but they rather place the Force of the Argument in it; and it is apparent enough of itself, since to fill Place, to occupy Space, to touch, be applied, or in some Sort penetrate one another is an Attribute proper and peculiar to Magnitudes. Therefore this Definition, if it be a Definition, does properly agree and square with these only.

But *secondly*, I say the *Equality* of Magnitudes is properly defined by itself alone. For since Quantity, and the consequent or concomitant Affections of Quantity, (*viz. Extension, Termination, Composition, Division, Mensuration, &c.*) do primarily and properly agree with Magnitudes; why may not *Equality* primarily agree with them too, and consequently be properly defined in respect to them? The Philosopher teaches that the Definition of a *Genus* does primarily and properly agree with the principal *Species* of those which are unequally attributed to it, and with the rest secondarily, consecutively and by similitude. *The Reason*, says (y) he, *of a Thing agrees with all its inferior Species, though not the same Way, but to these primarily, to these consecutively.* A Definition, taken simply, agrees properly with its first *Genus*, therefore a Definition ought to be made in respect of that. But are not the Values and Estimations of all other Quantities not only known but also named and denominated with Respect to Magni-

(y) Met. VII. 4.

tudes? Do not the very Words themselves of *Greater* and *Lesser*, *Whole* and *Part*, *Finite* and *Infinite*, *Continued* and *Discrete*, *Extended* and *Contracted*, *Proportion* and *Disproportion*, and such others, which are so often ascribed to other Quantities, draw their Origin no where else than from Magnitudes, and are secondarily transferred from these to other Quantities? And that not contingently and undeservedly, but necessarily and with the highest Reason. For certainly other Things accidentally subject to a mathematical Consideration have their Degrees, their Intensions and Remissions, but can no way be comprehended or expressed, but by making a Comparison of the Magnitudes, (in which they are, upon which they act, which they produce, or about which they are some Way conversant) and by applying Words borrowed from the Attributes of Magnitudes. *Ex. gr.* How can the *Weight* or *Momentum* of a gravitating Thing be conceived, or why is it called *so much*, *so great*, or *so little*, but as it is in so great a Body, or is capable to lift so great a Body, or sustain so great a Magnitude? How can it be understood to be *Divisible* or a *Whole*, but as the Body to which it inheres, or which it respects, has its particular Parts endowed with such a Virtue, or answering to such a Power? From whence is the Title of *finite* obtained, but either from the Terms of the Magnitude to which it belongs, or at least from the Bounds of the Body extended which it can raise or sustain? In like manner it may be predicated *Commensurable* and *Incommensurable*, because either its Subject or Object is found to be affected with *Proportion* or *Disproportion* to other Magnitudes in like manner endowed with Weight, with which it is compared. So also *Motion* is accounted *so much*, (*long*, *short*, *great*, *little*, either absolutely or comparatively) from the Magnitude of
Space

Space gone through, *so terminated* from the Limits of the Space so far as it is extended, *Mensurable* from its Dimensions, a *Whole* from its Compositions, and *Divisible* from its Divisibility. And the same Way (for I sometimes do purposely heap up more Examples than are requisite for illustrating the Thing proposed, having a View to the Usefulness of Things less common, that I may thereby gradually infill some (*z*) *Gust* preparatory to the Mathematics in general, and insinuate Notions which may be hereafter profitable for something) I say, the same way is *Time* conceived and denominated from the Magnitude of the Space run through by some Body determinately moveable, as the Sun or Moon, and it also borrows from them its *Terms, Extension, Proportion* and *other Affections*, with respect to the Magnitude of the same which it obtains. Also *Velocity* is computed from the Magnitude of the Space run through (not indeed absolutely, but comparatively, from the Magnitude of the Space passed over by another Body determinately moveable, *viz.* the Sun or Moon; *i. e.* from the Magnitude of Space gone through in so much Time) and is *limited, compounded, divided, measured*, and every way compared by a like Relation to the Magnitude of the Space; nor can it be scarce any other Way estimated. As to *Numbers*, it has been abundantly shewn, that they are no otherwise Partakers of Quantity and Proportion than as they are Symbols designing Magnitudes. Nor am I entirely by myself, and destitute of all Authority, when I affirm those Things (though oftentimes the Question and Subject I undertake are distinctly explained by none that I know of, having scarce any Guide or Companion to take off the Troublesomeness of my Passage through those rugged Paths; so that I am the

more pardonable if I seem sometimes to stumble or proceed with Difficulty) however I seem to have the chief of the Philosophers agreeing with me in this Business, whose Words are sufficiently for our Purpose. Since, says (a) he, *whatsoever is moved from one Term goes forward to some other Term, and every Magnitude is continuous, therefore Motion is so far the Consequent of Magnitude. For Motion is continuous by reason of the Continuity of Magnitude, and because of Motion Time is also continuous. For how much soever a Motion is, so much Time does also seem to have passed: But Priority and Posteriority are originally in Space from the different Position of its Parts; and since an Order of Parts is in Magnitude, the same will be also of Necessity in the Motion which analogically answers it; moreover a Priority and Posteriority is also found in time, because one of these is always consequent to the other (viz. as to the Affections and Attributes of this Sort).* Thus he clearly asserts the Continuity of Motion and Time, as well as the Quantity of Magnitude to be Consequents of the same Classis. Again, elsewhere, *Motion*, says (b) he, *follows Magnitude, and Time Motion as these are Quantities and continued and divisible. For because Magnitude is such, therefore Motion is so affected, and by reason of Motion, Time.* Thus the Philosopher in his Physics, so that he could have scarce pronounced any thing more appositely, plainly, or fully to our Purpose; except perhaps what he delivers in his *Metaphysics* be more express than these, and may tend more to strengthen and illustrate our Opinion. For thus he speaks concerning Motion and Time. (c) *Motion and Time are some Way said to be Quantities and Continuities, because the Things whose Affections they are (or to which they belong) are capable of Division. I mean not the*

(a) Phys. IV. 86. (b) Ib. IV. 18. (c) Met. IV. 13.

Thing itself which is moved, but that along which it is moved (i. e. the Space gone through). For because that is a Quantity, Motion is also a Quantity, and Time because of this. Thus does Aristotle give us his Suffrage and Authority. It is therefore just since other Quantities refer their Quantity, and Affections connected with Quantity, to Magnitude (at least its Knowledge and Comprehension) that also the Equality of the same (i. e. the Identity and Coalition of their Quantity) be taken from the Equality of Magnitude; and as they are Quantities by Analogy and Secondarily, so in like manner to obtain an analogical and borrowed Equality. Which will yet more manifestly appear not to be different to the Truth, to him that examines the Thing more closely and intimately, and consults the common Sense and Consent of Mankind. For ex. gr. if it be enquired of any Mortal (whether Philosopher or one of the Vulgar) what he means by saying *Two Times are equal*, I imagine he will return presently, and without Hesitation, that he means two equal Spaces run through by the same Body uniformly moved (as two equal Parts of the Sun's diurnal or annual Revolution) or by different Bodies carried by an equal Velocity. If what he signifies by the Equality of two Weights; he will say that the extreme Force of this is capable to elevate or sustain a Magnitude equal to another Magnitude of the same Species, which the extreme Force of another is capable to elevate or sustain: nor will they determine otherwise who are consulted about the Equality of Motions, Velocities, and all other Quantities whatsoever, always alledging the Equality of certain Magnitudes in respect of which the said Quantities are constituted and denominated equal. So that we can scarce distinguish or totally abstract the Equality of other Things from the Equality of Magnitude even in Thought, scarce by excluding

it can apprehend that they are equal, think or express how they are equal, or distinctly conceive what *Equality* itself is. Since therefore every other *Equality* does inwardly include and signify that, as by Nature prior and principal to itself, constitutive and definitive of itself, therefore other Quantities are only equal secondarily and less principally, dependently and consecutively, derivatively and by participation, by habitude or analogy. Whence that the Apprehension may be more clear, the Judgment more certain concerning other *Equalities*, it is first necessary to know and distinctly apprehend what the *Equality* of Magnitudes signifies and wherein it consists, and consequently that of right it ought to be first defined by itself. Which was the second Thing we undertook to explain and prove.

But, moreover, *thirdly*; Our *Congruity* does also agree with all Quantities whatsoever, as they are any Way *terminated, extended, compounded, divided, measured,* or admit other Affections of Magnitudes (as has already been sufficiently shewn), and especially by means of the *Congruity* of the Magnitudes in which they are, and which they respect. *Ex. gr.* It may be conceived that two moveable Points (or two any other moveable Things equal and similar) are carried with an equal Velocity along two Right Lines, or two Peripheries of equal Circles: it may be also understood that those Lines or Peripheries, as capable of *Congruity*, are applied to one another, so that the said Points or moveable Things are put upon one another, and consequently are congruous, as well in the Beginning as in the Progress of their Motion, by reason of their supposed equal Celerity or Velocity; therefore from the perpetual *Congruity* of the moveable Things and Coincidence of their Orbits, it is no way difficult to conceive that the Motions themselves are congruous, united, and coalesce;
and

and consequently that they have the same Quantity, or are equal to one another. In like manner, in the Course of any Body (suppose of the Sun or the Earth), the Quantity of whose Time is determined by an equable Motion, if two Points or Terms be conceived to be assumed by which the Beginnings of the Motions run through, and consequently of Times, may be computed ; and these Terms are conceived to be applied one upon another, as was just now shewn, so that thence the two Motions beginning from them may be congruous, then the Times themselves will be confluent, and pass on together. And if the Beginnings of two Years be conceived as conjoined, it will be easy to imagine them to exist together as proceeding with an equal Tenour, and as it were penetrate one another, and pass into one. Which is all one as if you should say, if two equal Things begin together, they will end together. Whence it will be lawful also to judge, what Way one Time can be really congruous with another Time : since Time is best measured and determined by the equable circular Motion, often repeated, of the same most noble and constantly moveable Thing, as (*d*) *Aristotle* observes ; *An uniform circular Motion is the best Measure, because its Number is most known.* For a Circle being measured so often by the periodical Revolution of the same moveable Thing does always continue one and the same : Hence by means of it *Motion* and *Time* (their Parts still beginning and ending in the same Point of the Periphery) are as it were united together and identified, and consequently are most perfectly congruous. Wherefore the Year comes back upon itself, Months and Days return, Ages are renewed, the Places and Periods of Seasons are restored ; and to use that

(*d*) *Phys.* IV. 14.

trite Saying of the Vulgar, *Time itself seems to be a Circle*, by reason of the circular and often repeated Motion which determines it. *As one and the same Motion* (says the (e) Philosopher) *may be performed again and again, so may one and the same Time, as a Year, the Spring, or Autumn.* But we have not Leisure to spend any more Words concerning Time. And the same Reason holds with Velocities, which in like manner by means of the *Congruities* of the Spaces passed over by them, are themselves congruous, and consequently may be demonstrated equal. Moreover if two heavy Bodies of the same Species, *ex. gr.* two equal Spheres of Water or Air, be supposed congruous by the *Mental Penetration* already explained; at the same time their Gravities or Weights will coincide, or become congruous, and by the same Reason be apprehended equal. In like manner *Congruity* may be some Way attributed to equal *Reasons* or *Proportions* themselves, as they all coincide and become the same with some one thing expounded by *Numbers, Lines, or some other Quantities*, which expounded Reason has a certain Resemblance of Space, in respect of the infinite Reasons it may represent and express, as it were receiving them all into and uniting them with itself. So also *Numbers* may be *congruous*, as far as they are equal, *viz.* by the *Congruence* of the equal Quantities which they represent and denominate. Consequently Quantities of every Kind, as they receive the other Properties of Magnitudes, so do they Congruity after their own Way, *i. e.* analogically, consecutively, and by Participation from the *Congruity* of the Magnitudes by which their Quantity is determined: and consequently the Definition of *Equality* resulting from the Supposition of *Con-*

(c) Phys. IV. 12.

gruity is not at all disagreeable to them; nay is so much the more agreeable, as *Equality* itself is agreeably and reasonably assigned.

But I proceed to the *fourth* Head of my Answer, *viz.* That it is necessary, or at least lawful, to define or explain separately the *Equalities* of other Quantities, *viz.* from the respective *Equality* of the Magnitudes in which they are, and about which they are any way conversant. For (as was before insinuated) the common Reason of such things as are unequally attributed (or predicated) does seem to require that the Things which are primary in their Genus, and consequently are as Measures of the rest be defined in the first Place by themselves, since the rest are declared of Consequence from a peculiar Relation to those that are prior to them. Thus again the Philosopher, who was most sensible of those Things: *Wherefore (t) it is first of all to be distinguished how many ways the Particulars are predicated of those Things that are unequally attributed (or predicated) and then to be explained how they are referred to that which is first in the said Genus (or Predicament;) for it is the Property of some Things to have, of some to affect, and of some to be other such ways attributed.* Thus, since *Equality* agrees with more Things than one, to Magnitude indeed originally and principally, and to other Quantities (*viz.* Motions, Times, Velocities, moving Powers) *secondarily* and less *principally*; therefore the Reason of that *Equality*, which agrees with Magnitudes, is first to be constituted; then it is to be explained how the *Equalities* of other Quantities are referred to it, and consequently they become separately defined. *Ex. gr.* equal Velocities, according to *Aristotle*, may be defined to be those whereby the same or equal Spaces are

(t) Met. III. 2.

passed over in the same Time. *That, (u)* says he, *is of an equal Celerity which is moved through an equal Space in an equal Time.* And again, *Those Things which pass over an equal Magnitude in an equal Time are of an equal Celerity.* Lo here Magnitude enters the Definition of Things of equal Celerity. So that it seems *Aristotle* himself thought it not amiss, by it to define the Equality of Velocity. And the same Way may equal Times be defined to be those, in which some noted Body carried with an equable Motion (*viz.* the *Sun* or *Moon* by determining the Time) performs equal Parts of its Course, which are coexistent with their equal Spaces. In like manner *equal Weights* (I speak absolutely without regard to mechanical Applications varying the *Momenta* of the same heavy Bodies) may, in respect of the Subject, be defined to be *those which are in Magnitudes the same in Specie and equal in Quantity*; in respect of the Object, *the moving Powers of equal Magnitudes the same way situated, as to all the Conditions of the Parts*; or *which can elevate the same, or equal Magnitudes of the same Species*; and *which are endowed with equal Forces and Powers.* Certain ancient Philosophers with *Aristotle (x)* did define equal Weights from their subjacent Matter, to be *those that consist of equal Principles, or of equal Particles of Matter.* Lastly, *Equal Numbers* may be defined *such as represent Magnitudes the same Way divided.*

By these and the like Means may the *Equalities* of all kinds of Quantities be defined, and perhaps this will be of great Use to their distinct Comprehension. There are not wanting Examples of the most excellent Authors, who not only pretend separately to define the *Equalities* of the said Quantities *equivocally, i. e.* by the same Word signify-

(u) *Phyf.* VII. 4.(x) *De Cælo* IV. 2.

ing different Things ; but also for the sake of greater Perspicuity *synonymously, i. e.* by different Words signifying the same Thing. For *Euclid* in the *eleventh Book* of his *Elements*, has defined *Equal solid Figures* to be *such as are contained within similar Planes equal in Multitude, and Magnitude.* And the great *Apollonius* (in the Beginning of the *sixth Book* of his *Conics*, which was lately translated from *Arabick* into *Latin*, and published by the excellent *Borellus*) has defined *equal Conic Sections* to be *such as being laid upon one another are congruous.* To pass by what I have already taken Notice of, that *Euclid* in his *Book of Gravity and Levity* has defined *those Things* to be *equal in Magnitude which fill the same Place* : And I am apt to think there may be some *Definition of equal Weights*, to which this concerning *equal Magnitudes* is preparatory. But what is near to our Purpose *Euclid* has delivered a different Definition of a *Part* concerning *Magnitudes and Numbers.* And the same Person, in the *fifth* of his *Elements*, has thought it of Use to define the *Analogy of Magnitudes* apart, and in the *seventh*, to give a different Definition of the *Proportionality of Numbers* ; from whence he seems to lay himself under a Necessity, whensoever he was to speak of other Quantities, to define also particularly their *Proportionality*, or at least to accommodate to them that which is delivered concerning the *Proportionality of Magnitudes.* Wherefore if it be amiss (which our Adversaries pretend) to define the same Word differently, as it is attributed to Things different in *Genus* or *Species*, we alledge that those famous Authors are guilty of admitting it, with whom we are not very much ashamed to err.

But at length (to finish our Examination of this Objection) I deny not, but the Reason brought would for the most part be of force, if any other

more general and convenient Notion of *Equality* could be assigned. But no other is to be found, at least none better than this, which depends upon any *Hypothesis* more evident to the Observation of the Sense, and Capacity of the Mind. Indeed (as we have noted in the preceding Lecture) the celebrated Man there mentioned has attempted two Notions, nor I imagine was he able to devise any better, which yet, as we have shewn, when examined do entirely fall in with this of ours, and the same Quantities, or the same *as Muches* of different *Things*, can be conceived no otherwise, than by some Sort of *Congruity* either *proper* or *analogical*. For that I may add this one Thing, to be some Sort of Illustration or Confirmation of what was then said; the specific Identity of Quantity is not sufficient to constitute *Equality* (for then all Circles, all Spheres, and every similar Figure would be equal) but a certain *Numerical Identity* is required for this, not indeed *actual*, but however *possible*, such as is best exhibited by that Coincidence and Coalition of Quantities, which emerges from *Congruence*. This Notion therefore does peculiarly square with Magnitudes (which are properly and primarily Quantities) and with other Quantities after some manner; and since other Quantities may and ought to be defined by the *Equality* of Magnitude, than which no other can be devised more convenient; these Things, I say, considered, it seems as if this ought to be willingly admitted and approved of against every opposite Argument. This principal Argument therefore being overthrown, which seemed to carry with it the greatest Appearance of Probability, we will now attack its second, which, as our Adversaries trust, is no less strong and invincible, but in my Opinion is much more weak and inconclusive.

The

The Possession or Repletion (say they) of the same Place is extraneous and accidental to Equality; nor are Magnitudes less equal, though they possess not the same Place, than if they do entirely possess it. And dissimilar Figures cannot occupy the same Place, except the Situation of their Parts be changed. But what (urge they) do Motion and Place and Transmutation relate to Equality? For a Pyramid even while it remains a Pyramid is no less equal (howsoever dissimilar) than when it is transformed; and while it remains elsewhere it is equal (however not in the same Place) no less than when it is moved in the same Place. Therefore Equality ought no more to be defined in respect to Place (when there is need of assuming a Transposition of Parts) than a Man because he may be Prince of Transylvania. Thus do they season their Argument as with Salt, lest it should perchance putrify or be of less Taste.

But I answer, that a Respect to the Space occupiable by itself is not accidental or extrinsic to any Magnitude, but is necessarily and intimately connected with it; to every act agrees an Habit, intrinsic and connate with itself, to the Power which it answers, and which it fills. I say it agrees not more essentially to the Nature of Magnitude, that it is capable of being terminated, extended, compounded or divided, or be the Subject of any other Attribute, than that it can fill so much, and such alike Capacity of itself, *i. e.* so much, and such alike, or an equal and similar Space. And from the Fountain of this Supposition do flow many necessary Mathematical Hypotheses; as may sufficiently appear from what has been already shewn. Moreover, though it does not happen necessarily to Magnitudes, as such, to possess this or that definite Place or Situation; yet it necessarily agrees with them, as equal, to be some way capable

ble of having the same Quantity, and consequently of filling the same Place; as well because it will plainly follow, that they in fact do occupy the same Space, since they actually have the same Quantity, as because this possible Identity can be no other Way conceived. Again, it is hence most clearly apparent that this *Capacity of possessing the same Space* does not happen contingently to equal Magnitudes, since to him that seriously weighs the Thing, Geometricians demonstrate nothing else concerning any Magnitudes compared together, as to *Equality* or any *Proportion*, but as they are capable of being congruous, or to occupy the same Place. When, *ex. gr.* *Euclid* shews the triple of a Cone to be equal to its circumscribed Cylinder; when *Archimedes* demonstrates the Superfice of a Sphere to be equal to four times the greatest Circle of the same Sphere; and when the same Person teaches that a Circle is equal to its Radii drawn into its Semiperiphery, it comes to the same, and their Arguments prove nothing else (to any who examines them from their first Principles) but that such Magnitudes are capable of being congruous to one another. For their Demonstrations depend particularly upon the *fourth* and *eighth Propositions* of the *first Book* of the *Elements*, where the *Equality of Triangles* is demonstrated from their *Possibility of Congruence*. Therefore, if a Capacity of filling the same Place be a Thing accidental to those Magnitudes, then it follows that the principal Geometricians have demonstrated nothing necessary to them, which sounds something harsh to Mathematical Ears.

Moreover, an *Occupation of Place* is not more extrinsically, nor less intrinsically conjoined with Magnitude, than *Motion*, or *Mutation of Place*; and as Magnitudes wheresoever placed are conceived equal, so Figures howsoever quiescent and unknown do
obtain

obtain and preserve the same Nature. Nevertheless no Geometrician refuses to define Figures by any Motion by which they can be generated with Ease. Thus *Euclid* thought fit to define a *Sphere* from the Revolution of a Semicircle about its Diameter, a *Cylinder* from the turning of a Parallelogram about its Side, and a *Cone* from the Rotation of a Triangle about its Leg; *Apollonius* a *conical Surface* universally from the Transit of a Right Line encompassing a circular Periphery; *Archimedes* a Conoid and Spheroid from plane Portions of conical Sections turned round their Diameter: And some Geometricians do the same way define at their Pleasure any Magnitudes (*Lines, Surfaces, and Solids*) from Motions circular, direct, parallel, or mixed. Which Definitions are not only the most lawful, but the best: For they not only explain the Nature of the Magnitude defined, but, at the same time, shew its possible Existence, and evidently discover the Method of its Construction: They not only describe what it is, but prove by Experiment, that it is capable of being such; and do put it beyond doubt how it becomes such. And the Reason is the same, the Virtue equal of this our Definition derived from *Congruity*; for it not only explains what the *Equality* of Magnitudes is, but that they are capable of being equal: It plainly discovers by what Means *equal Magnitudes* are effected, known, and explored, teaching it by a Method, which is most frequently in Use, and every where wont to be applied for the discerning and judging *Equality*. Therefore this Definition ought to displease none, who knows the Nature of Definitions, and observes how they always result from some possible Supposition.

Many Things do yet remain, which I thought to touch, but they are of light Moment, and their Solution may be easily perceived and deduced from what

what has been already said and insinuated ; so that what remains concerning *Congruity* and *Equality* may be easily supplied by your selves. For it is both troublesome to you and myself to continue thus long in a tedious Disputation about a Matter small and trifling. Nor would it be right to detain you from Arguments so much more sublime, which yet are to come. Therefore, most worthy Auditors, adieu for the present. In the succeeding Lecture I purpose to betake myself to another Province, in applying those Affections of *Proportion* and *Analogy*.

L E C T U R E XIII.

Of the erroneous Comment of Proclus, and others upon the eighth Axiom of the first Element, &c.

TH E last I handled of the Attributes and Properties of Magnitudes, which are subservient for Mathematical Hypotheses was *Congruity*, and have treated at large, that the Notion of *Equality* is most rightly fetched thence. The Subject now seems to require me to pass elsewhere, but such is my Infelicity, I can't dismiss this Business before I adjoin one or two little Remarks, by way of Confectary, relating to the farther Declaration and Use of my Purpose.

First then I observe, that, from what has been delivered, may be discovered a remarkable Error of *Proclus*, and most Interpreters, who have commented after him, upon the *eighth Axiom* of the *first* of the *Elements*. The *Axiom* is thus expressed, *Things which are congruous to one another are also equal.*

equal. This *Proclus* denies to hold convertible universally. *It does not* (says he) *truly agree with all Magnitudes, but only with those of the same Species, or such as are most perfectly similar.* And with him agrees *Borellus*; *But convertibly* (says he) *that those Things which are equal are congruous to one another, is not true in all Magnitudes; but in those of the same Species, as Right Lines between themselves, and the Circumferences of equal Circles, as Proclus observes.* But this Exception more diligently looked into, is not only unnecessary, but (which seems wonderful to have escaped such sagacious Persons) will be found utterly false. For by *Congruity* they there understand either an *actual* or *potential Congruity*. But whether Way soever it be taken their Assertions differ from Truth. If they be taken concerning *actual Congruity*; they are most evidently convinced of Falsity, because neither all equal Right Lines, nor the Circumferences of equal Circles, nor Magnitudes howsoever equal or similar, are actually congruous, but are often most distant as to Place; as much *ex. gr.* as the *Antarctic Circle* is distant from the *Arctic* and contrary to it in Situation, though alike in Species, and altogether equal in Magnitude: If concerning *potential*, it appears from what is already demonstrated, and not what is to be demonstrated, that it is also falsely affirmed *that some equal Magnitudes are not congruous.* For on the contrary it is most true that all equal Magnitudes howsoever different in Specie, or unlike to one another, are capable of *Congruity*. It is indeed true, that Magnitudes of the same Species, and most perfectly similar to one another (*viz.* as Right Lines, Circles described with equal *Radii*, and equal rectilineal Angles) do admit an *actual Congruity* after a certain peculiar Manner, *viz.* the Order of the Parts being retained, and the Situation no where varied; also their

Q

their *possible Congruity* is easily apprehended, and perhaps immediately inferred from their Definition. But this does not less truly agree with all other equal Magnitudes which are capable of being rendered most accurately congruous by the Translation of certain of their Parts, and the Mutation in Part of their Figure; *i. e.* the Parts of one (which differ nothing from its Whole) will exactly possess the Space of the other. But the Retention or Alteration of Figure neither adds any Thing to, nor derogates from the *Equality* or *Congruity* of Magnitudes; nor is it of any Consideration here, whether the Comprehension of possible *Congruity* be easy or difficult. For it is as true which is lawfully demonstrated by a thousand Chains of Arguments, as that which is perceived at first View, or immediately inferred by one only Syllogism. *Euclid* indeed has demonstrated the *Congruity* of any even rectilinear Figure with a determinate Square, and (as far as possible has attempted the same) of any solid Figure contained within plane Superficies, *i. e.* he has taught or investigated the Method of measuring them. *Archimedes*, proceeding farther has compared Circles, and circular Sectors, also curved, conical, cylindrical, and spherical Superficies, and demonstrated them to be congruous with one another by the most evident Consequences. When *ex. gr.* *Archimedes* demonstrated that a Circle is equal to a rectangular Triangle, whose Basis is equal to the Radius of the Circle, and Cathetus to the Periphery (or which comes to the same, to the Square whose Side is a mean Proportional between the Radius and Semi-periphery of the Circle) he did nothing else (we will find) but demonstrate that the Area of a Circle or regular Polygon having an indefinite Number of Sides may be divided into so many minute Triangles which are equal to just so many little Trigons of the said Triangle;

Triangle ; and the *Equality* of those Triangles is demonstrated in the Elements from *Congruity* alone. From whence consequently *Archimedes* has demonstrated the *Congruity* of a Circle with a Triangle howsoever dissimilar they be to one another. Also when the Superfice of a Cone is by the same Person demonstrated to be equal to the Area of a Circle, whose Radius is a mean Proportional between the Side of the Cone and the Semidiameter of the Basis ; he demonstrates nothing else (as is plain by having Recourse to the first Origin of Demonstration) but that this Superfice does as it were consist of an Infinity of little Triangles, every one of which are congruous to as many particular Triangles composing the said Circle. Thus the *Dissimilitude* of Figures is no Hindrance to *Congruity* ; but whether they be *similar* or *dissimilar*, so they be *equal*, they either always are, or ought to be, capable of *Congruity*. Therefore the said *eighth Axiom* can either be no Way, or else every Way, convertible ; no Way, if what is there accounted *Congruity* design *actual Congruity* ; every Way if it be only taken for *potential*, i. e. *Those Things which are capable of Congruity are equal and convertible* : After which manner Reason does rather require it to be understood. For it is better thus to explain that most useful Axiom, to hold every Way convertibly ; than to be no Way capable to be converted ; and to contain an essential Affection of Magnitude, than only to respect an accidental Property. For to be actually congruous has no Affinity to the *Nature of Magnitude* or *Equality*, but happens to them contingently, and (since an Act always argues a previous Power) is applied for no other Cause, but as a *Potential Congruity* may be known by it, which only does intimately agree with *Equality*, and is perpetually reciprocal with it. For as it is reckoned connate and most closely connected

with Magnitude *not to be actually divided, but to be divisible*, and this *Divisibility* is distinguished and known separately from actual *Division*, however fortuitous or arbitrary; so it accidentally happens to *equal Quantities* as such, that they are actually congruous, but it agrees inseparably and perpetually that they are capable of being so; but that Act is subservient, and therefore is wont to be applied for shewing this Power. Therefore *Proclus* and most others treading in his Footsteps do wrongly explain this *Axiom*, not taking sufficient Notice of the Difference between *actual* and *possible Congruity*, only respecting actual *Congruity*, which is not here to be attended to.

The excellent *Clavius* is one who has kept himself free from this Contagion; whom therefore his most learned Countryman *Tacquet* has wrongfully blamed. *Clavius*, says he, *has not converted this Axiom rightly, for it is false that those Things which are universally equal to one another are mutually congruous; for dissimilar Magnitudes may be equal, yet they will not be congruous; but if they be similar and equal, it will hold convertibly.*

But I rather admire the singular either Knowledge or good Fortune of *Clavius*, who has happily avoided the common Error, and wholly omitted this Exception which depends upon so false a Foundation, and has truly explained that *Axiom*, though not fully and sufficiently clear. But in this I have been too prolix, though I am silent as to some Things.

Secondly, I observe that the *Axioms* which relate to *Equality* may be demonstrated from this Definition of *Equality* laid down: which argues its Convenience and Excellence. For *Axioms* as certain *Theorems* (which has been often admonished) ought to be capable of being demonstrated from the lawful Definitions of the Terms of which they consist.

consist. Therefore *Apollonius* has illustrated that which *Ramus* calls the *most bright Sun in the Mathematics*, *That those Things, which are equal to the same, are equal to one another*, by a Demonstration fetched from hence. Let the two Magnitudes A and C be each singularly supposed equal to a third Magnitude B. I say the Magnitudes A and C are equal. For since by the Hypotheses the Magnitudes A and B are equal, the same (by the foregoing Definition of *Equality*) are capable of being congruous; therefore let them fill the Place Z. Also since the Magnitudes C and B are equal by the Hypothesis, if C be put upon B occupying the Place Z; also C (from the Definition of *Equality*) will be capable of occupying the Place Z. Therefore both A and C are capable of filling the Place Z. From whence reciprocally (from the Definition of *Equality*) A and C will be equal. Q. E. D.

But *Proclus* objects against this Definition, that it depends upon the Assumption of those two Axioms, *Those Things which possess the same Place are equal*; and *those Things which occupy the same Place with another, do occupy the same Place between themselves*: Both of which he affirms to be far more obscure, and difficult to be granted, than the Conclusion proposed to be demonstrated. But in Defence of that great Geometrician I briefly answer. *First*, it is apparently false, that the Consideration of Place or Space is more obscure and unknown to us than that of *Equality*. Since, from what is before proved, *Equality* can only be illustrated from it. Also *Congruity*, or a Possession of the same Place, may be supposed, because it may be discerned to be possible by Sense; but *Equality* does not immediately occur to the Sense, but results from some supposed Comparison; therefore the Notion of *Congruity* is clearer than that of *Equality*. And since, *those Things which occupy the*

Q 3

same

same Place are equal is the most commodious Definition of *Equality* (as methinks we have sufficiently proved) it will therefore be more simple and evident than any other Proposition including *Equality*: As the Definition of a Triangle is more simple and clear than any Theorem about a Triangle. Secondly, as to the other Axiom, *Those Things which occupy the same Place with another, do occupy the same Place between themselves*; I deny that any Thing can be clearer, much less that this is more obscure than the proposed Conclusion. For, if tryed to the bottom, it will be found a Proposition plainly identical, and differs no more from it, than *that Peter is Peter*; for it is reduced to this Proposition without changing its Sense, but only for the sake of Perspicuity giving Names to the Magnitudes; as *Z* the Place common to *B* and *A* is the same with *Z* the Place common to *B* and *C*. Or this Categorical Proposition, *Those Things which occupy the same Place with another do occupy the same Place between themselves*, may be reduced to this equivalent Hypothetical Enunciation, *If the Magnitude A occupy the Place Z belonging to the Magnitude B, and the Magnitude C occupy the Place Z belonging also to the Magnitude B, then the Magnitudes A and C do occupy the same Place Z*. Where that which is supposed in the Antecedent is repeated in the Consequent. And what Proposition, I beg can be more manifestly true than this? Certainly not this, *Those Things, which are equal to the same, are equal to one another*, because it must first be known what *Equality* is, and what is signified by it, before the Truth of this Proposition can be comprehended. But yet *thirdly*, I deny that the said trifling and silly Axiom is presupposed, or applied in a Demonstration. We only infer, because a Magnitude is supposed to occupy the Place *Z*, that

C which

C which is equal to that Magnitude is also capable to occupy the same Place Z ; which immediately follows from the foregoing Definition of *Equality*. Nor do we use any different Principle. Let any one take Notice : To be sure *Proclus* uses all his Strength to oppose the Demonstration of *Apollonius* : And he gravely concludes : *All Axioms ought to be delivered as immediate, and clear by their own Light, manifest and meriting Assent from themselves. For he who uses Demonstration in the most evident Things does not establish their Truth but weaken the Evidence, which we have without Learning in our preconceived Notions.* To which Opinion, as to vulgar Use, I willingly subscribe, nor is there any need to confess that it is too scrupulous to examine Things commanding so easy an Assent. But I think it is not unuseful, to shew by some Experiments for the further Declaration of the Genius of Demonstration, the Nature of Science, and Diversity of Principles, that the utmost Rigour does even require the Demonstration of Axioms, that they in reality are capable of being demonstrated, and that Definitions well constituted are serviceable for demonstrating them. Nor do I think him worthy of being impeached of *Madness* or *Pride*, who attempts such a Thing, either for these Causes, or the Exercise of his Genius, of which Things notwithstanding a very severe *Aristarchus* among the Moderns (I wish not guilty of the same Vices himself) lets not to accuse such an one, and consequently *Apollonius* himself a Man of the greatest Sagacity and most consummate Learning in the Mathematics. However relying upon the Example of so great a Man, I will not be afraid myself to demonstrate, entirely from what has been said, the two next Axioms to the said first. The *second* Axiom is this ; *If equal Quantities be added to equal Quantities,*

tities the Sums (or Wholes) will be equal: Which I thus demonstrate. Let A and B be two equal Magnitudes, which consequently (from the Definition of *Equality*) are capable of *Congruence*, and of filling the same Place. Let them therefore occupy the Place X, and let the Magnitude C be added to A, whose Place let be Y. Therefore $X \vdash Y$ is the Place of the Sum $A \vdash C$. Also let the Magnitude D equal to C be added to B, from whence in like manner (from the Definition of *Equality*), D will be capable of filling the Place X: and consequently $B \vdash D$ will be capable of occupying the compounded Place $X \vdash Y$; *viz.* the same which $A \vdash C$ is capable of occupying. Therefore (from the Definition of *Equality*) $B \vdash D$ will be equal to $A \vdash C$. Q. E. D. By a like Discursus will be demonstrated the next subsequent Axiom; *If equal Quantities be taken from equal Quantities the Remainders will be equal.* For again, let there be two equal Magnitudes A and B, of which consequently there may be a common capable Place X. Let the equal Magnitudes C and D be taken from those, whose common Place also let be Y. Therefore the remaining Place $X - Y$ will be a common capable Place to both the remaining Magnitudes $A - C$ and $B - D$. Therefore the Remainders $A - C$ and $B - D$ are equal. Q. E. D. And by the same Method may any Theorem (or Axiom) pertaining to abstract *Equality* be demonstrated, by help of the said Definition, which shews its Excellence and Convenience. But dismissing this Observation, I remark,

Thirdly, That, from what has been said, it may be easily perceived what is *Equal to*, what *Greater*, and what *Lesser than* another: For scarce any of these can be any way explained but from a Reference to an opposite *Equal*, or more immediately from a Relation to *Space*. 1. With Respect to
Space,

Space, that will be called *Unequal*, which is always and necessarily *Incongruous* with another, *i. e.* which being any how applied to another (either at the same time, or successively, or by mental Penetration, or retaining the Situation of the Parts, or changing their Order any of these Ways as explained above) will no way exactly coincide with it, but either exceed or fall short of it. Consequently of two *unequal Species*, that will be *Greater*, which being thus applied to, or put upon the other, will exceed it, *i. e.* will occupy the whole Space of the other, and some farther Space besides; or a Part of which will be congruous with the Whole of the other, or fill the whole Space of the other: that *Lesser*, which being applied to the other will fall short of it, or coincide with a Part of the other, or will occupy a Part of the Space which is possessed by the other. 2. But with respect to an *Equal* that will be called *Unequal*, which contains in it another (or what is equal to another) and something besides; or is so contained in another (or in something which is equal to another) that something remains over and above. That, *viz.* is *Greater* which contains another (or which is equal to another) and something besides: That *Lesser* which is so contained in another (or in that which is equal to another) that something is still remaining. Or with Mr. *Hobbs*, a *Magnitude* may be not unelegantly defined *Greater than a Magnitude* (he says a Body than a Body, but it is better to speak more universally) *when a Part of that is equal to the Whole of this: Lesser, when the Whole of that is equal to a Part of this*; though perhaps something is wanting in those Definitions. For it may be objected that they answer not those unequal Magnitudes, of which one comprehends the other. Which yet may be easily excused or pardoned, because every Magnitude is reckoned *Equal* to itself
in

in the most perfect Manner, and *Identity* does eminently contain *Equality*, which is every where supposed in the Demonstrations of Geometry. Or these Definitions may be corrected and supplied by expressing them thus; *A Magnitude is Greater than a Magnitude, when a Part of that is equal, or the same, with the Whole of this: Lesser, when the Whole of that is equal, or the same, with a Part of this.* Which Definitions of *Inequality, Greater or Lesser*, will also agree *analogically* with other *Quantities*, each its own Way, (*viz.* with *Motions, Times, Velocities, Weights, Numbers,*) as has been largely explained concerning *Equality*.

I will only advertise one Thing concerning the said *Inequality* thus to be taken, that the *Excess* and *Defect*, or that which abounds or supplies, is here always meant of Things *homogeneous*. For *Quantities* of a different Kind are not capable of being compared together in respect to *Equality* or *Inequality*. Which will be afterwards more distinctly explained, when we come to treat of *Proportion*.

But shall I never extricate myself from these Quirks and Trifles? Shall I always spend my time in examining what is of no Value? In so plentiful an Harvest, so rich a Vintage, so great a Store of most important Disquisitions, why do I only glean the scattered Ears, search the neglected Boughs, and gather the fallen Grapes? When a Chace after the important and difficult Things in the Mathematics is offered, a Chace so full of Variety, so pleasant, and so certain; wherefore do I dwell so long upon those little Questions, like one hunting after Flies? I shun things of Consequence, sport in serious, am gravely ridiculous, studiously seeking after, and nicely repeating and inculcating every the slightest Matter. Shall I thus incessantly follow so many distant By-ways, so many uncouth Turnings, and shall I never return again into the beaten Paths

Paths of the King's high Road? Shall I grow old in these outer Courts of *general Matters*? Shall I perpetually tarry in the Entrance of the Sciences? Shall I always stick in the Threshold? Shall I only knock at the Doors of the Mathematics, and never enter within the Walls of the House, nor penetrate its more sacred Recesses? Shall I ever be upon the Parley, ever skirmish at a Distance, and never engage Hand to Hand, or come to a decisive Battle? What do I but raise Mists and Doubts, sow Strifes and Contentions, raise Storms and Tumults in that Science, which promises, which boasts of nothing but what is clear and evident, certain and tried, calm and serene? And by disputing more freely, and bringing many Things to the Scrutiny, I seem to detract and derogate from the Certitude and Evidence of the Mathematics, which is so contrary to Jarring and Contentions? Thus am I wont to upbraid myself, and perhaps also others do the same; at least not without some seeming Cause, or Appearance of Justice.

Notwithstanding I am able to alledge something in my own Excuse to wipe away those Reproaches; and since so much of the Time destined for this Lecture is now passed over, contrary to Expectation, so that I am unable, though not unwilling to enter upon another new Subject: I humbly beg of you to pardon this, and indulge me with a little of your Patience while I am in some sort defending these Trifles, and explaining the Reason of the Design, I have hitherto gone upon. As to these little Niceties I answer, that those Things are not always small which seem so; since the Stars appear very small, and the Sun not great; we are therefore to have a thorough Knowledge from whence the Appearance of a Thing beheld comes, and whither it tends, before its Magnitude

nitide can be judged of. Those Things which are small in Bulk, are sometimes endued with vast Strength, and those which contain nothing in them notable, do often draw after them very great Consequences. The Origins of the greatest Things are almost constantly small; the largest Stocks grow from small Seeds, immense Rivers swell from small Fountains, and the Nature of *Truth* and *Error* is most remarkably fruitful; a vast Light is on every Side diffused from small Sparks of Truth, and a huge Crop of Errors springs from the least Root of Falshood: In the Sciences especially, from slender Threads are suspended the greatest Weights, nor are the least Things contemned without the greatest Damage. As a whole Machine perishes and becomes unfit for Use, by the misplacing of one Wheel, and a huge Elephant often perishes by the Breach of a little Vein; so sometimes one only Notion, which may seem small and barren, if ill placed and badly understood, will from a fruitful Offspring of Consequences derive upon any Science a vast Confusion, a gross Darknes, and a manifold Cause of Error. *Aristotle* (who also maintains his own Accuracy and strict Diligence in some more minute Things) has wisely observed in the Words most worthy of Notice which are extant in the *fifth* Chapter of his first Book *de Cælo*: *Any little Wandering is presently encreased and multiplied to ten thousand times greater, by such as recede from the Truth. As if one should affirm that some least Magnitude may be given; such an one introducing a Minimum, will overturn the greatest of Mathematical Things. And thence it happens that every Principle is more prevalent by its Power, than by its absolute Magnitude. From whence what in the Beginning seems little, in the End will become very great.* So dangerous is it in the Judgment of the Philosopher to lay aside
all

all Care of the least Things, which have not only their Account, but also oftentimes an Advantage by no means to be slighted; especially in those Sciences, which climb e're we are aware from low and almost ridiculous Beginnings to an incredible Bigness and Height. I am not therefore to be very much blamed, if I sometimes seem to be more curious and prolix than there is occasion for, in things seemingly of not much Weight, since Reason requires, that I should add some Light to those Things, that I know to be of very great Moment.

But as to those Controversies which I frequently move, none, I suppose, can suspect that any of them detracts from the Certainty of the Mathematical Sciences; since they are conversant about Things very remote from the Foundation of the Mathematics. These Questions do scarce touch the outmost Skin of Geometry, much less reach its inward Bowels. These Rams do not shake its Principles, nor overthrow, or at all disturb, its Reasonings. While Contentions and Strifes, Clamours and Janglings do arise, and make a Noise, in its Confines and Suburbs, a deep Peace and profound Silence dwells within the Walls, and in the Citadel itself; nothing is there heard of Controversy or Opposition.

Albeit we take Examples as well elsewhere, as from the most modern Controversies we have handled; it has been disputed what was the genuine Notion of *Equality*, from whence it is most conveniently defined, whether it may be demonstrated, what Axioms are assumed about it; but no Body doubts whether those Axioms be true; and consequently no Body will dissent from the Conclusions inferred by their Help. It is enquired concerning the Nature and Number of Principles, and concerning the Method of obtaining the
Knowledge

Knowledge of them, whether they are innate or comparate, whether they depend upon general Induction, or particular Observation only; but yet their Truth remains safe and sound, and is placed beyond all Doubt. It is doubted and controverted whether *Euclid* gives a good Definition of *Parallelism* from a Negation of the Meeting of Right Lines infinitely produced; but I believe no Body has denied, but there may be Right Lines, which by this Means can never meet together, and which are not unaptly stiled *Parallel*. It is denied by some whether the same *Euclid* has justly assumed it for a Principle, that two Right Lines will meet one another from that Part, on which the said Lines do make the internal Angles with an insisting Right Line lesser than two Right Angles; yet so that the Truth of the Proposition itself is called in Question by none. Also Geometricians contend, and the Matter is still undecided, whether *Euclid* has made a right Choice in that Affection of Proportionals by which he defines them; yet the Truth of that Proposition is preserved under the Form of that Theorem laid down, to which no wise Man refuses his Assent. I could produce many more Examples, by which it may appear, that the Differences among Mathematicians are no Prejudice to the Certainty or Evidence of the Mathematics, but do rather argue their invincible Truth and pure Brightness, which no Tumults of Disputations can overthrow, no Clouds of Discord overshadow. Nor is this to be wondered at, since it is not here contended about the Truth of *Principles*, but about the *Order* of some Propositions; not about the *Certitude* but the *Method* of Science, rather only about the Exteriors of Philosophy than of the Mathematics; the Knowledge of which is indeed of no little Weight, as conducing to a full, distinct and accurate Comprehension of

the Things handled in the Mathematics, but when compared with the Principles of Geometry (these Principles, while the Truth of which continues safe, no very great Inconvenience can befall the Mathematics, no geometrical Conclusion can be rendered invalid); I say, when compared with these, the Things about which we are contending can be thought little or nothing at all: So true is that Saying also here,

———Minimas rerum discordia vexat,
Pacem summa tenent———

*Discord (we see) does vex the least of Things,
The greatest are at Peace———*

Neither therefore do I think this Contentiousness or Inclination to dispute about the Things belonging to this Science, to be of any ill Consequence, since it affects not their Stability, but is useful to their Accuracy. Especially since my Endeavours are for no other End but that by disputing I may utterly eradicate and remove all Causes of Disputation, weighing as far as I am able the Reason of Things in the Ballance of Experience; and reducing all Things from metaphysical Niceties to common Sense. Nor do I invent many Questions of myself, but find them somewhere (though for the most Part lightly touched), interposing my Opinion supported with some Arguments, and committing the ultimate Decision to your own Arbitration. I have also religiously kept and observed that most equitable Rule of (d) *Aristotle*, which, if I remember well, was quoted before, but is worthy of being often repeated. *Things said will be more credited if the Reasons be first heard on both*

(d) De Cælo I. 19.

Sides of the Question. For it does not become us to give Sentence without hearing the Cause, or condemn any Side unheard. They who are willing to judge well of the Truth ought not to be Adversaries (on either Hand) but Arbitrators. Than which Sentiment nothing is more just, more sacred, or more prudent.

Moreover I may be excused for dwelling longer than ordinary upon these general Things by way of Proem and Prelude: *First*, Because among them many Things are found not unworthy of Observation, nor every where obvious and vulgarly used, but either for the most Part do not occur, or else are more sparingly explained; and also because of certain Paradoxes, useful for whetting the Genius, and exercising the Judgment. Again, a distinct Conception generally seems to contribute very much to the easy Understanding and perfect Knowledge of what follows. For so many famous Problems being published by Mathematicians, so many excellent Theorems demonstrated about various Principles, *viz.* about *Magnitude, Number, Space, Motion, Time, Velocity, Weight*, about *Composition and Division, Termination and Figuration, Equality and Inequality, Symmetry and Assymetry, Proportion and Proportionality, Similitude and Dissimilitude, Determination and Indetermination*, and other such like Things; is it not of great Use to have the previous Notions of these *genuine and adequate*? Such as though I do not perfectly teach; at least I give an Occasion of acquiring, to you who more maturely examine the Reasons proposed. However it is of no small Concern to the Students of those Sciences to be familiarly acquainted with their common *Genius and Nature*. And indeed I have often considered that the most learned Men do sometimes speak crudely and improperly about Mathematical Things, and sometimes reason

6 falsly

falsely from a less attentive Consideration of these *Generals*, having imprinted depraved or confused Notions upon their Minds. Besides, I willingly submit to such of you, I consult your honest Pleasure, who, being less fit for the more abstruse Mysteries of the Mathematics, do differ; and yet are both desirous and capable to receive some Taste of those most pleasant Sciences, to behold something of their Pleasure and Profit, as it were at a Distance; whom I would by no means send away deprived of their Hope, disappointed of their Labour, and troubled at the too great Difficulty or apparent Obscurity of Things: Nor do I deny but I have for the most part suited both the Matter of my Discourse, and the Manner of expressing it to your Capacity, and many Things are said, which I would otherwise have been silent of, many Things passed by, which I would otherwise have said.

But I am afraid the dry Subtilty of the particular Demonstrations, which the inward Parts of the Mathematics abound with, their extreme Rigour requiring the closest Attention, and their Way of arguing, will somewhat offend and deter the most. Those Subjects (not to dissemble) are in my Opinion not so convenient for publick Lectures of this Kind, therefore I willingly make some Delay in these which are not so barren and unpleasant; yet studying to intersperse certain Things belonging to the more inward Part of the Mathematics, and henceforward I shall continue so to do.

Moreover while we are prosecuting those *Generals*, I imagine some Time is to be granted them, who give their Attendance to these Lectures, and who, being not content just to taste of those Sciences, are desirous to immerse themselves deeper, and wholly wash in the Sea of Mathematical Learning, and be thoroughly instructed in the *Elements*

of *Geometry* ; to which I earnestly intreat such not to be negligent in applying their Studies ; otherwise I believe it will be impossible from these more abstruse Instructions, nay or scarce from the more clear of any Mathematical Discipline, to draw any Thing intelligible to the Hearers ; but like an enigmatical *Sphinx*, or some obscure *Heraclitus*, I shall seem to utter mere Riddles, and be involved in thick Darknes. But if I knew that the most of you were initiated in the Elements of *Geometry*, I could I hope with some Fruit and Pleasure to yourselves, either lay open the lowest Foundations of singular Disciplines, and exhibit the principal Rules established by their Demonstrations ; or, what is very delightful to be known, and especially becomes the Students of an University (on which sort of *Persons* it is incumbent above others to imbibe the Study of the ancient *Wisdom* and Disciplines from their Fountains) could search out the Method of the old Mathematicians in inventing and demonstrating their Theorems ; or (which is the principal Scope and highest Apex of the whole Mathematics) could exhibit certain general Methods, demonstrated and illustrated by Examples, for the more easy Resolution of all Sorts of Problems, the Invention of Theorems, and the Construction and Demonstration of these as well as those ; many of which Sort of Methods most useful and elegant, unknown to the Ancients, at least not committed to Memory, has the Industry of the Moderns invented and brought to Light. Of which Sort, by the Way (besides the new Method of *Analysis*, chiefly cultivated by *Vieta* and *Cartesius*, almost equal to every soluble Question) is *Cavellarius's* Method of *Indivisibles*, which already has been, but never sufficiently can be, praised ; the Method *Circa Maxima & Minima*, also very useful for the most expeditious Solution of very
many

many Problems; the various general Rules of investigating the *Tangents* of *Curves*; the Ways of producing *Curve Lines*, and investigating their Properties from the *Dependance* and *Composition* of *Motions*; the Ways of comparing different *Series* of *Magnitudes*, *increasing* or *decreasing* in a certain Order, and from thence determining the *Measures* of innumerable *Planes* and *Solids*; the general Rules for readily finding the *Centers* of *Gravity* in all Kinds of Magnitudes, also of easily deducing the *Dimensions* of the Magnitudes themselves from the *Centers* of *Gravity* found; with some few other Things of lesser Note. Any of which, if I should now undertake to handle, I am afraid the most Part would not perfectly understand my Meaning from the vanishing Words of an Oration; at least (to deal familiarly with you) if I may be permitted to make an Estimate of other People's Capacities from my own, I confess myself so dull and unapt that I can much easier understand that which is plainly laid before my Eyes, than that which is insinuated through the treacherous Caverns of my Ears.

Lastly, To put an End once to this excessive Loquacity, as for my own Part, it would be much easier for me (but I must not do it) to draw certain particular Subjects out of the wealthy Store of the Mathematics, or demonstrate some singular Conclusions, (of which a vast Plenty are common at every one's Hand) than to float on this Ocean of *Philosophico-Mathematical* Disquisitions. I do not therefore, in the Prosecution of these *Generals*, sacrifice any Thing to my own Leisure, but rather to your Profit; I do not gratify my own Desire, but, as far as I can guess, for the most Part yours: I act at your Pleasure, being always ready and most intent, as far as I am able, to satisfy and obey your ingenuous Requests, or more justly;

your Commands. Thus I have pleaded my Cause without being cited ; I have framed an Apology without being accused or challenged by any I know of ; but how can I clear myself of Breach of Faith, and from the Non-performance of the Promise, by which I obliged myself in this Lecture to treat of *Proportion* ? So it happens in many Things we oblige ourselves, and promise others what we can hardly perform ; we more easily engage our Faith than discharge it. Indeed to one who runs over this Subject in his Thoughts, so many Difficulties offer themselves to be explained, so many Questions to be discussed, and so many different Sentiments to be considered, that I can scarce sustain the entering so great a Sea for want of Time, the Term being so near an End. Nevertheless, by this Prelude I may perhaps gain something, and pave the Way for expounding a most subtle Matter. And since I have said nothing to the Purpose in this, I will endeavour to compensate the Defect in the two remaining Lectures.

L E C T U R E X I V .

Of the different Acceptations of the Word Measure.

THE last Attributes of Magnitudes we considered were their *Equality* and *Inequality*, whose genuine Notions we have asserted as far as we are able. *Reason* or *Proportion* now follows in Order, because this is almost nothing else but a certain Determination of *Equality* or *Inequality* resulting from the Comparison of Quantities. For
since

since generally speaking Quantities, which are comparable with one another, may receive infinite Modes of *Inequality*, by receiving from *Equality* (which is simple, and as I may say of one Mode), therefore the *Determination* expressed in Numbers, or other fit Terms, of some of these particular Modes appropriated to the Things compared, is wont to be called their *Proportion*, whereby is signified, whether they are *equal*, or upon what certain peculiar Account they are *unequal*. Yet this principal Property of Magnitudes, that we may the more distinctly and clearly explain it, seems to require both, that we first expound *Mensurability* that noble Affection of Magnitudes, because of the *Symmetry* and *Assymetry* which necessarily intervenes with the Doctrine of *Proportion*, and that we consider a little the *Aptitude* and *Ineptitude* of Quantities for *Comparison*, which Things being well understood it will be easy to judge of the Nature of *Proportion*.

As to *Mensurability*, this, as to its Name, deserves to be more curiously weighed, because from hence a Name is imposed upon that *Mother* and *Mistress* of the rest of the Mathematical Sciences, which is employed about Magnitudes, and which is wont to be called *Geometry* (a Word taken from ancient Use, because it was first applied only to *measuring the Earth* and fixing the Limits of Possessions) though the Name seemed very ridiculous to *Plato*, who substitutes in its Place that more extensive Name of *Metrics* or *Mensuration*; and others after him give it the Title of *Pantometry*, because it teaches the Method of measuring all Kinds of Magnitudes. Though neither do these attribute a Name proper or adequate to it, since this Science does not only contemplate that Affections of Magnitude, but also some *others* with which nothing is interspersed belonging to

Measure. For it does not only respect the *Quantities* of Magnitudes, but investigates and demonstrates their *Qualities* also (*i. e.* with what *Disposition* of Parts, with what *Figure* they are endowed, whether *right* or *curved*, *plane* or *gibbous*, *direct* or *inflex*, *round* or *angular*) in like manner how they are *situated*, *i. e.* what *determinate Position* they obtain. I say it equally considers the *Species* and *Similitudes* of Magnitudes, as well as their *Measures* and *Proportions*. Moreover, as to Practice itself, it not only teaches to *compare* Magnitudes together by *measuring* them, but also to *constitute*, *describe*, and *transform* them, and to find their *Centers*, *Diameters*, and *Tangents* without any regard to *Quantity*.

From whence, by the Way, it appears that *Geometry* is not badly defined by most, *The Art or Science of Measuring*; or *the Science of Magnitude, as it is mensurable*. These Descriptions which are delivered by Mr. *Hobbes's* Censurer, Mr. *Hobbes* does somewhere carp at, and pretend to correct, but produces no better Definition, nay one more elaborately unfit and evidently guilty of the same Fault. *Geometry* (says he) *is the Science of determining the Magnitude of any Thing not measured, by its Comparison with another measured Magnitude or Magnitudes*. But I ask those Definers of our Science; when the Geometrician *bisects a Right Line, or a Rectilineal Angle*; when he *erects or lets fall a right-lined Perpendicular from a given Point*; when he *draws a Parallel to a given Right Line through a given Point*; or when he *draws a right-lined Tangent to a given Curve*; when he *constitutes an equilateral Triangle, or Square, upon a given Right Line*; when he *describes a Circle through three given Points, or circumscribes a Circle about a given Triangle*; when he *investigates the Center of a given Circumference, or the Focus of a given Conic*

Conic Section: I say, when he does many such Things, and *resolves Problems* respecting only the *Position* of *Magnitudes*; whether does he perform the Office of a Geometrician as he ought, and when he compares *Magnitudes* together this Way, as to their *Quantity*, what *Relation* have they to any *Measure*? Why, none at all; he only determines the *Situation* of *Lines*, and enquires after the *Position* of *certain Points*. I pass by that the Geometrician equally considers the *Motions* by which *Figures* are generated, &c. These *Definitions* therefore are inadequate and incongruous, and founded upon false *Prejudices*. He therefore assigned this Science a more apposite *Compellation*, whoever he was, that thought it ought to be called *μεγεθεικὴν*, i. e. *the Science conversant about Magnitudes*, and which *speculates*, i. e. *enquires, invents, and demonstrates* all its *Affections*. Consequently it is not ill described by *Proclus*; *The Knowledge of Magnitudes and Figures, and their Limitations; Also of their Reasons, Affections, Positions, and Motions of every Kind*. Yet it is not to be denied, but a great Part of this Science, and its chief Use, consists in this, that the *Quantities* of *Magnitudes* are known and computed by *Comparison*; i. e. that they are capable of *Measure*. Wherefore we will spend some Labour in explaining this *Affection* of *Magnitude*.

First then we will endeavour to unfold the *Ambiguities*, and various *Significations* of the Word *Measure*, with its consequent *Mensurable* from *mensurare* to *measure*, and other such paronymous Terms; and that, as well because a thorough Knowledge of this is both pleasant and useful of itself, as lest we fall into *Error* by being deluded and distracted by the various *Significations* of so dubious a Word, which sometimes happens; and lastly that we may have a more distinct Knowledge,

ledge, what is the principal Notion of this Property. And indeed if we regard the popular Use of the Word *Measure*, there scarce occurs any Word wrested to more Significations, or that more frequently obtains, or more aptly admits of Metaphorical Senses. For instance, to a *Good Man right Reason*, and the *Prescripts of Virtue* are called the *Measure* of the Life and Manners; to an *Epicurean earthly Pleasure*; to the *Covetous Man Gain*; and to the *Ambitious Temporal Power and Glory*; because mostly the Designs, Endeavours and Actions are by those Men directed and adapted to such Things: The *Custom* or *Opinion* of the *People* is called the *Measure* of *Decency*, as to the external Circumstances of Things: *Common Use* the *Measure* or *Rule* of *Speech*, and the *Signification* of *Words*. With (a) *Aristotle*, *Law* is described the *Measure* of *Justice*, because a Thing is declared *just*, according to its Agreement with it. Also with the same, *Science* is termed the *Measure* of *Things*, because the just Limits of (b) *Things* are determined by it, and it shews how they are related to one another, and to what they tend. With *Cicero*, it is put metonymically for the Judgment itself, or the *Faculty* whereby the *Quantity* of *Things* is discerned or estimated, when he says, *Whatsoever falls under the Measure of the Ears is called Number*; i. e. whose *Quantity* may be judged by the Ear. Also *Measure* is used for the definite *Quantity* of any Thing, as in those golden Verses of *Juvenal*,

————— *Mensura tamen quæ*
Sufficiat censûs, si quis me consulat edam :
In quantum fitis atque fames & frigora poscunt ;
Quantum, Epicure, tibi parvis suffecit in hortis,

(a) *Top. VI. 2.*

(b) *Met. X. 1.*

Quantum

Quantum Socratici ceperunt ante penates.
Nunquam aliud natura, aliud sapientia dicit.

Which may be thus rendered,

*Yet if I'm ask'd what Measure may suffice
Of Store ; I answer, just as much as will,
O Epicurus, keep thee from th' Assaults
Of Hunger, Thirst, and Cold ; what grows within
Thy little Gardens will afford enough,
Or what the Houses heretofore contain'd
Of the sage Followers of Socrates.
Nature and Wisdom always speak the same.*

And elsewhere the same *Juvenal*,

——— Sed quæ præclara & prospera tanti
Ut rebus lætis par sit *Mensura* malorum ?
——— But what Conditions are
So fortunate and happy as t' obtain
A Measure, just the same of good and ill.

To which I add *Lucan*,

——— Fuit hæc *Mensura* Timoris
Velle putant quodcunque potest———
*This was the Measure of their Fear ; whate'er
Is in his Power, they think is in his Will.*

i. e. the Romans feared all that from *Cæsar*, which they saw in his Power ; and because he was able to do all Things against them, they feared all Things from him. And no otherwise is that Sentence of *Hesiod* to be taken, where he commands Benefits to be returned in the same *Measure*, *i. e.* the same *Quantity* wherein they are received ; or even with Interest $\alpha\upsilon\tau\omega\ \tau\omega\ \mu\acute{\epsilon}\tau\rho\omega,\ \kappa\alpha\iota\ \lambda\acute{\omega}\iota\omicron\nu$: Also in the sacred Writings the Word $\mu\acute{\epsilon}\tau\rho\nu$ *Measure* has sometimes the same Sense ; as in *Rom. xii. 3.* According as God hath dealt to every Man the Measure of Faith, *i. e.* according to the certain and definite *Quantity* of Faith, which he hath dispensed to every one,

But

But it would be endless to rehearse all the trite, common and improper Acceptations of this Word. Yet one or two of the more noted of these deserves to be lightly touched, as coming nigher the Notion of *Mathematical Measure*, and in part *serviceable* to it. Such in the first Place is that, whereby *Measure* every where designs the Quantity of a Thing justly, duly, and conformably to Nature or Reason, which, if it either exceed or fall short of, is accounted for deformed, vitious, or monstrous; and consequently in respect of which, every Virtue in Morality, every Beauty in Nature, and every Utility in Art is estimated. In Morality, I say, every Virtue is reckoned as well from a certain *Moderamen* of the Affections as *Mediocrity* of the Actions, *i. e.* from their just and due Quantities discovered by the Prescript of Prudence, or right practical Reason. And in like manner Vice seems to consist in the Excess or Defect of this Quantity, and to be nothing but an *Exorbitance* or *Irregularity* of the Affections and Actions, from the *stated Measure* of the Manners. None of you can be ignorant that *Aristotle* constitutes the Form of Virtue and Vice in these. And *Plato* (contrary to what some suppose) most expressly gives his Assent the same Way in these Words, (a) *That which exceeds or falls short of the Nature of due Measure or Mediocrity, either in Words or Deeds; shall we not say that it constitutes the real Difference of good Men from ill? To which Words Socrates puts his φαίνεται (it is manifest).* And to this may be referred that of *Hesiod*,

Μέτρον πᾶσιν ἄριστον, ὑπερβασίη δ' ἀλεγεινή

Measure is best in all Things, and whate'er Exceeds the Bounds of that, is counted bad.

(a) See the Dialogue inscribed Πολιτικός.

Whatsoever

Whatsoever agrees with or comes up to this *Measure* is said to be a *Mean* or to preserve a *Medium*, and is esteemed Praise-worthy ; and whatsoever recedes or falls from it is termed irregular, and is wont to be taken for a Vice. From whence every where they who moderate and govern their Affections well, especially their Ambition and Animosity, are said to be *Temperate* ; nor is any Policy to be accounted more worthy of Praise. But I unwittingly fall into *Ethics*, I will retreat ; only give me leave to subjoin *Plato's* Saying concerning *Pleasure* in Comparison with *Knowledge* and *Reason*. *Nothing*, says he, *can be more difficultly reduced to a just Measure than Pleasure, and nothing is more easily contained within due Bounds than Knowledge and Understanding.*

Also in natural Things, *Shape* or *Beauty* is rated according to this *Measure*, *i. e.* according to a certain just Magnitude. Thus he is esteemed monstrous, or deformed, that exceeds a certain determinate Stature of Body by a Giant-like Tallness or Thickness, or is disagreeably slender or short, or has some Parts immoderately jutting out or sinking inwards, or has any Thing deficient or redundant in Number or Bigness.

In like manner in artificial Things it is judged from such a Measure what is comely and convenient. For almost all Arts aim at nothing else, but to give the Things, about which they are conversant, a certain just Quantity, accommodated to certain designed Uses or Appearances. Whence *Plato* makes all Arts to be *Portions* of the *Art of Measure*, teaching to direct their Endeavours to a Medium, that Practitioners may render their Works useful and comely. *The Art of Measuring*, says he, *is so divided into two, that one of its Parts contains all the Arts, that compare together Numbers, Lengths, Depths, Breadths, and Velocities ;*
and

and the other the remaining Arts respect what is moderate, decent, and opportune, and whatsoever Things aim at a Mean, avoiding the Extreams.

But we have exceeded our Bounds concerning this popular Acceptation; yet we will just glance at another of kin to it, according to which, *Measure* designs some *stated Pattern*, commonly known and proved, exposed to the Senses, or comprehended by the Understanding, by which the Quantities or Values of other Things ought, or are wont, to be examined. This Sort of *Measure* is twofold, *viz.* *Natural* and *Arbitrary*. The *Arbitrary* is such as is propounded by public Authority (as *Vessels, Weights, Rules*) for the Sake of Conformity or Agreement; from which other Measures do borrow their Right, Name, and Reason of *Measure*, and are no otherwise *Measures*, than as they agree with these Originals. But the *Measure* of every natural Thing is that which is the first and most perfect in that Genus: As the *Divine Nature* is the *Measure* of *Goodness* and *Wisdom*, because God alone is originally of himself *good* and *wise*, and other Things are only so far Partakers of *Goodness* and *Wisdom*, as they have any Agreement with, or Resemblance of the *Divine Goodness*. Every Thing, according to *Plato*, has such a *Measure*, the *eternal* and *indefectible Idea of itself*, *viz.* some most exact Pattern, from its Similitude or Correspondence with which it is accounted *true, comely, and perfect*, and if it disagree the least from it, it is so far *vicious, deformed, and imperfect*. And in the end of his *Philebus* he disposes *Measure* in the first Place among the prime and eternal Things. *Thou shalt tell all, O Protarchus, both sending Messengers elsewhere, and thyself speaking to them that are present, that Pleasure is a Thing to be put neither in the first nor second Rank; but it is first to be spoke concerning*

concerning *Measure*, what is agreeable and opportune to *Measure*, and all such Things as are by Nature eternal. Where by *Measure* he seems to understand the original Idea of every Thing : but I spend Time in these Things.

Let us now leave these popular Things, and come to the Significations of *Measure*, which are used among Mathematicians. And the Definition or Description of *Measure*, which (u) *Aristotle* delivers, agrees in Part with all these. *Measures* is that by which the Quantity of a Thing is known. But because this Knowledge of Quantity may be differently apprehended according to various Degrees and Respects, consequently the Name of *Measure* is taken more or less extensively.

And first, *Measure* is often put for any Thing, which any way shews or notifies the Quantity of another, and denotes nothing else but a certain Argument, or Sign, or undoubted Criterion of some determinate Quantity. Thus the Arch of a Circle described from the angular Point as a Center, and intercepted between the Legs of a rectilinear Angle ; And in *Spherics*, the Arch of a Circle described from the angular Point as a Pole, and intercepted between the Sides of the spherical Angle, is the *Measure* of both the said rectilinear and spherical Angle ; because if the Quantity of that Arch (*i. e.* what Part it is, or what Reason it has to the whole Circumference of the Circle, or its Quadrant) may be known by an Instrumental *Mensuration*, or any other way, the Quantity of the said Angle will be consequently known from thence, *i. e.* what Part or what *Proportion* it has to four Right Angles, or to one Right one. Nor on the other hand may any Angle having its Vertex in the Center or Pole of a Circle be less

(n) Met. X. 1.

properly said to be the *Measure* of the circular Arch ; because, as far as by Hypothesis or Discursus it has a known *Proportion* to four Right Angles, it will shew the Reason of the intercepted Arch to the whole Circumference. For some do wrongly say that an intercepted Arch is the proper Quantity of its Angle ; when the Arch is no more the Quantity of the Angle, than the Angle of the Arch ; nay this is no more a *Measure* than that, either on the Part of the Thing, or from common Use ; since their Quantities are carried on proportionally, connected necessarily, and shew one another reciprocally : And by the same Reason circular Sectors are named the *Measures* of Angles, and these of those. Moreover by this Means not only Magnitude is termed the *Measure* of Space, Space of Motion and Time, but interchangeably also, Motion and Time are called the *Measures* of Space, and Space of Magnitude ; for as the Quantity of the Magnitude occupying the Space is known by a prior Knowledge of the Space ; so far will the Quantity of the predeterminate Space run over be discovered by Motion or Time. So that if it can be known how much Time is passed since the Rising of the Sun, thence we may gather how much of its Periphery the Sun has run through in the mean Time. Which Permutation of Space, Time and Motion in respect of *Measure* (x) Aristotle has plainly taken notice of. *We don't only, says he, measure Motion by Time, but also Time by Motion, for this Reason, because they are interchangeably defined by one another. And we measure also Magnitude by Motion, and Motion by Magnitude ; for if a Walk be great, we are said to have gone a great Way, and on the contrary, if the Way be great, to have*

(x) Phys. IV. 12.

had a great Walk ; in like manner we say the Time is great if the Motion be so, and the Motion great if the Time be so. Farther to abound with Examples, the throwing of a Dart or Stone is this Way a *Measure* of Space, though more imperfectly ; for as far as the Strength of the Thrower is known by a former Experiment, it may be thence known, how much Space is between his Station, and the Fall of the Thing thrown. Nay, since every Thing, every natural Agent, has a determinate Sphere of its Activity, it may as such some Way discharge the Office of a *Measure*, viz. Since Fire exerts a Power of Heating to a certain Distance and is perceived to effect nothing beyond that ; since a Flower, or any odoriferous Body, disperses its Vapours of Smell to a certain Place ; since a visible Object is beheld to a certain Distance, and disappears farther off ; since the Sound of the Voice is perceived by the Ears placed within a definite Bound, beyond which it is insensible ; if it first be known by a particular Experience how great the Radius of every such Sphere of Activity is, some Judgment may be made from thence concerning those Interstices, *i. e.* the Quantities of those Powers being found will become a Kind of *Measures* of the Spaces. Thus, it is commonly said by Historians, that the Distances of Places were computed from an Estimation of the Space, which a quick-footed Man was able to go over in some assigned Time : And also that Mariners judged the Tracts of the Sea, and Distances of Ports, from the Time of Sailing performed by a constant equable Wind. So Astronomers do very accurately measure Time by numbering the returning Synchronisms of a suspended Plumb-line. Also Shadow (though one of the most obscure and subtle Things, and almost nothing at all) is a *Measure* of this Kind in many respects ; its Motion upon

Dials shews the Quantity of Time ; its Magnitude received upon a Wall discovers the apparent Magnitude of the Sun ; and lastly, it is subservient for measuring the true Magnitude of the Sun in Eclipses. Thus there is scarce any Thing but either is or imitates such a *Measure* ; and (what is especially to be noted) Things the most different in Genus or Kind may be the *Measures* of each other, according to the Latitude of this Acceptation.

But *secondly*, something more strictly, that is called a *Measure* from the Quantity of which the Knowledge of Quantity does necessarily depend, as it is measurable ; consequently the Quantity of this is no otherwise known, than it can be known from a former Knowledge of that. Which Sort of *Measure* in respect to the foregoing already explained, may be said to be *natural*, and *a priori* ; because it is not assumed so arbitrarily, but is required necessarily, and suggested by Nature itself for investigating the Quantity of the Thing measured. Thus Magnitude is the *Measure* of Space, because the Quantity of Space can be no otherwise comprehended, than by measuring, or some Way sufficiently computing some real Magnitude occupying it. And Space is such a *Measure* of Motion and Time. The Space, I say, run over equably with a certain Velocity by some noted moveable Body is the *Measure* of Time (at least *mediately* by the Intervention of Motion) for it cannot be known how much Time is passed, but by estimating the Quantity of such a Space. *Ex. gr.* an Arch of the equinoctial Circle intercepted between two Meridians passing through the Point of the Sun's Rising in the Horizon and the Center of the Sun, is the natural and genuine *Measure* of the Time elapsed from the Rising of the Sun to the given Instant. And according to *Ptolemy's* Doctrine, an Arch in the Sun's Eccentric, is such a *Measure* of the

the Time of the Year, which is taken in, while the Sun is passing that Arch. In like manner the *Measure* of the Velocity, wherewith any moveable Thing is carried uniformly, is the Space gone through in an assigned Time; for hence we make a certain Conjecture how much Space that moveable Thing will pass over in any other determinate Time; and by the same Means we will be able to discover the Quantity of the Velocity.

But *thirdly*, in a yet stricter Manner, that is said to be a *Measure*, which, by reason of a certain extraordinary Determination, Simplicity, Knowableness, or most easy Comprehension, may be most aptly applied for determining the Modes of Things, or comparing Quantities together. Thus when *infinite Curve-Lines*, or *indirect linear Orbits*, are extended between two assigned Points or Places; though the Distances of these are computed from themselves, yet a *Right Line* by reason of its Unity and Simplicity is said to measure that Interval. And though innumerable unequal Right Lines may be drawn from a *given Point to a Right Line given in Position*; yet a *right lined Perpendicular*, because it is simple, and one, is said to measure the Distance of the *Right Line* from thence. For the same Cause the Distance of a *Right Line subtended in a Circle*, or of a *lesser Circle in a Sphere*, from the Center of the Circle or Sphere, is estimated by a *Perpendicular* let fall from the Center to the *Subtense* or *Plane* of the said *lesser Circle*. By like Reason the Distance of *Right Lines parallel* to one another is measured by any *right lined Perpendicular* intercepted between them; and the Distance of *concentric Peripheries* is computed from an *intercepted Portion* of any *Radius* drawn from the *common Center*, because this is always of the same Quantity. So also *Apollonius* (or the *Arabian* that interpreted his Works) in the

fifth Book of his *Conics*, names the Right Line intercepted between the Vertex and Point in the Diameter assigned, a *Measure*; because there occurs none simpler, or greater, for determining the Quantity of the other Branches. The same Way, because among Superficies a plane one is most simple and uniform, and among right lined Figures the Square is the simplest and easiest known; therefore a Square is usually called and accounted the *Measure* of superficial Figures, and their Quantities are referred to this, as far as it may be done. And the same Reason holds of a Cube in Solids, to which the Quantities of other Solids are reduced, because of its manifest Determination, and the easily conceivable Property of its Nature. A right Angle also obtains the Place of a received *Measure* in rectilinear Angles, because it is in some Degree more known than others, obtains a peculiar Name, and seems to include a more simple Relation of the insisting Line to that upon which it stands. So lastly Geometricians endeavour to reduce all curved and compound Lines to a Right Line, which is the simplest of all Lines, and determine their Quantities from some Relation which they obtain to this. And the same Method is observed in other Quantities: For because the diurnal Revolution of the Heavens, or (according to the more received Hypothesis in our Times) of the Earth is the most constant, uniform, and known of all Motions; therefore it is assumed and used for the *Measure* of other Motions, Times, and Velocities. And the Quantities of other Weights are by the Masters of Statics reduced to the Quantity of Gold as the heaviest Body, or of Oyl as the lightest. And in every other kind of Quantity, for Convenience sake, such an one is always required for a *Measure*, as is remarkable for its Simplicity or Mobility.

But

But *fourthly* to come nigher our Purpose, that is wont to be called a *Measure* which is assumed to render something more known and determinate to us than it was before, and is expounded with this Design, that other Quantities coming into Consideration may, as to Quantity, be compared with it, or with one another by means of it; *viz.* that it may be investigated how often this contains, or is contained in those, or what Proportion those obtain to these; and consequently how they are related one to another, so that their Quantities may be some Way known and determined, which were before unknown and indeterminate. Thus a *Foot*, a *Palm*, a *Yard*, a *Cubit*, a *Pace*, a *Gill*, a *Quart*, a *Bushel*, and the other Measures, whose Names among the Vulgar do signify a certain Length or Capacity, are therefore *measuring Magnitudes*, because their Quantity is commonly supposed known and determined by Compact; from whence the definite Quantity of other unknown and indeterminate Magnitudes may be judged by a Comparison with these, from Congruity, or a proper Discursus. Thus also, when the Quantity is required of Chord-Lines subtending the Periphery of a Circle, or of regular Figures inscribed within a Circle, the *Radius* of the Circle is wont to be assumed for a *Measure*, as the most known, and perfectly determined of all the Lines in a Circle; and is supposed to be divided into as many equal Parts, as are needful for Use, or as many as are needful ought to be allowed to every particular Chord or Side by the Application of Geometrical Theorems, or by whatsoever other lawful Method it is examined and computed: Or some Equation is sought by an apt Ratiocination, by which the Relation of the said Subtenses or Sides to the Radius of the Circle may be notified or expressed: Or if it may be done, the very Chord

or Side which is sought, is actually drawn and delineated, that its Proportion to the Radius may be estimated from a sensible Comparison, or known by an organical or instrumental Mensuration : Or at least two other Lines are applied, whose Proportion is the same with the Proportion of the said Line to the Radius ; and consequently whose Reason being found, will discover the Reason required. For the Measuring or Dimension of Quantities may be performed, and the Reason of the Quantity proposed to that known or determined by Nature expressed and estimated these different Ways, *viz.* by Numbers, or by some Equation, or by a sensible Computation from the same Terms immediately, or from other analogical ones exposed to the Sense ; whose Dimension also found by suitable Instruments will exhibit the numerical Proportion. But these Things are to be explained more fully and distinctly elsewhere. To return to more Examples : By a like Means the Square of the Radius or Diameter is applied for finding the Quantities of the Areas of the rest of the said Figures, as the *Measure* with which they may be compared. Also after the same Manner, in estimating and comparing together the Sides, Superficies, and Solidities of the *regular Bodies*, the Radius of the Sphere is taken, in which they are included or inscribed, and these are compared with it, its Square, or its Cube, that their mutual Proportion may be found and laid by for Use. Thus also is the Semi-diameter of the Earth commonly applied by Astronomers in their Search after the true Distances of the Stars from one another, and their true Magnitudes, as a certain *common Measure*, to which their Quantities may be reduced. As when the Moon is said to be distant so many Semi-diameters from the Center of the Earth, its Diameter is said to be equal to so many Parts of the same Semi-diameter.

And

And the same of others. Nor (to observe by the Way) in this Acceptation of *Measure* is it of any Consequence at all, whether the Magnitude sustaining the Place of a *Measure*, be greater or lesser than that which is measured : as in the Examples above the *Radius* is lesser than a *Chord* of 120 *Degrees*, or the Side of a regular Triangle inscribed within the Circle, but greater than a *Chord* of 36 *Degrees*, or the Side of a Decagon inscribed within the same Circle. And the Semi-diameter of the Earth is greater than the Semi-diameter of the Moon, but far less than the Distance of the Moon. Also if there be assumed a Geometrical Pace, by a just Comparison of it may be known the Length of a Foot, as well as that equal-to a Furlong or a Mile. Here is no Regard how the Quantities so compared are affected with the Measure expounded, so that their Proportion can but be expressed by Numbers : For this Way all Magnitudes are commensurable to one another, though the Proportion of some be inexpressible in Numbers; *i. e.* one of them may be assigned to which the Quantities of the rest may be referred, and measured by it. Though the Reason of the *Radius* to a *Chord* of 90 *Degrees*, or the Side of a Square inscribed within the Circle, can be precisely explained by no Numbers, yet the Quantity of this may be compared with the Quantity of that, and so far they are commensurate. These Things, I say, I observe by the Way, because of the following Acceptation, which is peculiar to the Mathematics, and of most frequent Use; according to which,

Fifthly, a *Measure* is more strictly taken for a *Magnitude*, which some Number of Times taken does constitute and compose another *Magnitude*, or which being some Number of Times taken from another *Magnitude* leaves no Remainder, but entirely exhausts it. By some Number of Times is here to

be understood once, or oftener, according to Unity or some determinate Number: From whence it appears that a *Measure* thus taken will never exceed the Thing measured, but either is equal to it, or some aliquot Part of it, *i. e.* which being some Times repeated according to any Number composes the Whole; or some Number of which does constitute and make up the Whole; or some Number of which being taken from the Whole leaves no Remainder. Thus a *Foot* is the *Measure* of a *Geometrical Pace*, that of a *Furlong*, and a *Furlong* of a *Mile* and a *League*; because a *Foot* taken *five Times* makes a *Geometrical Pace*, and subducted away *five Times* destroys it: a *Pace* taken a *hundred and twenty five Times* makes a *Furlong*, and a *Furlong* repeated *eight Times* compleats a *Mile*. So also a *Minute* measures an *Hour*, an *Hour* a *Day*, a *Day* a *civil Month*, and a *civil Month* a *civil Year*. But a *Day* does not thus measure a *natural Month* or *Year*, nor a *Month* a *natural Year*. Because 365 *Days* are short of a *natural Year*, and 366 *Days* exceed it, and so for others.

And thus are *Measures*, and the Words paronymous to it always understood in the *Elements* of *Geometry* (though no Definition of *Measure* is to be found there, which seems a Wonder to some) as when an *Aliquot Part* is defined in the beginning of the *fifth Book* to be a *Magnitude of a Magnitude, a less of a greater, since it may measure the greater, i. e.* Since, if it be some Number of Times taken, it does so exhaust the Whole, that nothing remains. For the Word *καταμετρεῖν* does there in the Original signify to *measure perfectly*. As also the simple Verb *μετρεῖν* does ordinarily denote the same; and most evidently in the Beginning of the *tenth Book*, where *Commensurable Magnitudes* are defined to be *those that are measured (μετρεῖσθαι) by one and the same Measure, i. e. each of which the*
same

same Magnitude taken some Number of Times does constitute, and taken away some Number of Times does destroy. And a perfect Division (or Subtraction, simple, or multiple, which leaves no Remainder) is always signified by μέτρησις. Thus also the Philosopher seems to use this Word, when he (y) says, *The Whole which is measured (μετρήσιμον) seems to be nothing but a Measure taken some Number of Times.* Yet (z) Aristotle in his *Metaphysics* affords one most strict Acceptation, according to which *Measure* designs that which, being the first and least in every Kind, is wont to be applied to a Thing indivisible to Sense (or the least Thing usually divided) for discovering the Quantity of others, viz. as an *Unit* in *Numbers*, a *Grain* in *Weights*, a *Farthing* in *Money*, a *Diesis* in the *Intervals of Sound*, an *Inch* in *Lines*, are Measures, by Way of Eminence. Aristotle testifies that among the *Greeks* their *smallest Measure* in Length was a *Foot*.

But I have not Time to pursue these Things. Nor is it now lawful to adjoin which of these is the principal or most proper Notion or Acceptation, according to which *Mensurability*, the Affection of Magnitude now in Hand, ought to be understood. And many other Things are now to be passed by. For the Time reminds us to draw to a Close, and I am afraid lest some Wit smite me with an obvious Pun, and say, While I am talking about *Measure*, I take the least Heed to the *Measure* of my Discourse.

(y) *Phys.* IV. 14.(z) *Met.* X. 1.

LECTURE XV.

Of the Acceptation of the Words paronymous to Measure, viz. Mensurability, Mensuration, Commensurability and Incommensurability.

IN the last Lecture we were not negligent in our Endeavours to expound the different common Acceptations of the Word *Measure*. From whence it will easily appear how many Ways the paronymous Terms, *To measure, mensurable, &c.* may be accepted; *viz.* as many Ways respectively, as the Word *Measure* may be taken. It remains that we consider according to which of these Ways especially *Mensurability*, the Affection of Magnitude we are treating of, ought to be understood, and what is its primary Notion. Two of these Ways which are familiar to Mathematicians are especially to be considered and carefully distinguished, to which all others may be referred,

The *first* is more extensive, but most proper, from which, as we shall shew, *Geometry* has taken his Name, and which according to its Office it principally respects; in which respect it denotes *to measure, notify, or determine the Quantity of some Magnitude with Regard to some other homogeneous Magnitude howsoever more known to us, or more determinate, by declaring, exhibiting, and representing its Proportion to this in Numbers, or some other comprehensible Way: i. e.* by signifying how great a Part that is of this, or this of that, how they are unequal, how much that exceeds or falls short of
this,

this, or by any other like Way. *Ex. gr.* Supposing any Longitude hitherto unknown to us, if we can by any Means agreeable to Reason (*viz.* either by an *instrumental Operation*, or *mental Ratiocination* depending upon lawful Hypotheses, or Conclusions already demonstrated) find what Relation it has in Quantity to any expounded Longitude well known by us; how often it contains, or is contained in that; how often it may be taken to exceed or fall short of that; whether it is to it as one Number to another, or as one Right Line I am able to make, to another Right Line I am able to make, or as the Radix of some Equation subject to an Analytical Enquiry, and resolvable by Art, then we are said to *measure* that Longitude: Which Sort of Dimension of direct Longitudes is named *Mecometry* and *Eutbumetry*, or by those mongrel Words *Longimetry* and *Altimetry*. In like manner supposing any plane Figure; when we infer what Proportion it has to another plane Figure exhibited (*viz.* a *Square Foot*) and represent it by Numbers or some other Way, we are said to *measure* it: Which Kind of Dimension of Planes may be termed *Empedometry*, and is vulgarly and barbarously stiled *Planimetry*. By a like Reason when we compare some Solid with a *cubical Foot*, or with an equal and similar Cylinder, or some other known Body, and find its Reason to that; this is called *Stereometry*. Also such a Comparison of the Sides and Angles of a Triangle, by which, from certain Sides and Angles known in the said Triangle, the Reason of the other Angles may be found to a right one, or the Proportion of the other Sides, to the one assigned and known, this is called *Trigonometry*. And when we endeavour as exactly as we are able to determine the Proportion between the Periphery and Diameter of a Circle, or between a Circle's Area, and the Square of its Diameter; that is termed *Cyclometry*. From which

†

Examples,

Examples, brought designedly, it appears, as I said, that this Notion of *Mensuration* is the most genuine and primary, since the principal Parts of the Mathematics are especially conversant about it, and do consequently receive their Denomination from it.

With respect therefore to this ought the Affection of Magnitude to be taken, which we are now treating about, called *Mensurability*, (in Greek μέτρησις, *Measuring*, a Word more ambiguous, confounding the Power with the Act), which denotes nothing but that a Magnitude is capable of being compared with other Magnitudes of the same Kind, so that its Quantity however otherwise unknown and indeterminate is capable of being some Way known and determined from the Relation which it obtains to them. For this is connate and essential to every Kind of Magnitude, as far as every Magnitude is to any other homogeneous Magnitude, (*viz.* a Line to a Line, a Superfice to a Superfice, a Solid to a Solid) necessarily either equal or unequal after a certain Manner, which is knowable on the Part of the Thing, and determinable of itself; though the Knowledge of it is very often difficult to be acquired, and sometimes can be no Way accurately comprehended.

Neither does this Affection agree with Magnitude only, but also (as we have particularly shewn in other Affections) to all other Quantities whatsoever (*Motions, Times, Velocities, Weights*) analogically and their own Way, as far as their Proportion to one another can be determined, exhibited, or expressed, and consequently the Quantity of one discovered from its Relation to the known Quantity of the other. *Ex. gr.* We *measure* Time, when we shew it to be equal to so many Days, Hours, or Minutes; or be so to another known Time, as that Right Line, or that Periphery of
a Circle

a Circle is to this, whose Proportion to one another we know. We *measure* Velocity, when in a Time having such Proportion to another known Time, we shew that the Space passed over is so much with Respect to a Space known; *i. e.* when we shew that Velocity to have a known Proportion to a known Velocity. Lastly, we *measure* Weight, when we find, how great a Magnitude of a known Gravity it can elevate or sustain, or what Proportion it has to another known Weight. And the same Reason holds in all other Quantities. But that this Property may be yet more clearly known, we will subjoin somewhat concerning certain Properties of *Measure*, and the *Way of measuring Magnitudes*.

The *first Property* of the Kind of *Measure* we are now upon, is, that it be *homogeneous* to the *Thing measured*; *i. e.* that it be capable of being compared with it according to Congruity and Incongruity, Equality and Inequality, Excess and Defect, Addition and Subtraction, and lastly according to Reason and Proportion, *viz.* that a Line be capable of being the *Measure* of a Line, a Superfice of a Superfice, a Solid of a Solid, a Time of a Time, a Velocity of a Velocity, and a Weight of a Weight. But a Line cannot be the Measure of a Superfice, a Superfice of a Body, a Magnitude of a Time, or a Time of a Weight, according to this more accurate Acceptation of *Measure*. Indeed that more loose and unauthorized Notion of *Measure* declared above, according to which every Thing that any Way argues, indicates, or notifies the Quantity of another is said to measure it, I say, that may happen even to *heterogeneous* Quantities, and is not seldom attributed and applied to them by Mathematicians; which Way a Line may and is wont to be named the *Measure* of Time, a Superfice of Velocity, a Body of Weight;

Weight; and reciprocally Time the *Measure* of a Line, Velocity of a Superfice, and Weight of a Body.

But yet those Acceptations are to be distinguished with great Care, lest we unwittingly fall with Mr. *Hobbes* into many Labyrinths of Difficulties and Errors, by not observing that Distinction, nor taking Notice of the Ambiguity of this Word. Such Mistakes as these; That a Line has Proportion to a Time, and by like Reason a Superfice to a Velocity, a Solid to a Weight; because a Line does in some Sort measure Time, a Superfice Velocity, and a Solid Weight. That the Quantities of all Things are the same or homogeneous to one another; because all Things are subject to the same Measures, *viz.* Lines and Numbers. Lastly, that one Quantum may be the Quantity of any other, *viz.* that a Line may be a Quantity of Time, Velocity and Weight, nay of a Superfice and a Body, because it determines the Quantity of these as a *Measure*. Which monstrous Absurdities seem to have proceeded from no other Fountain than a Disregard of this Distinction: as we will shew very briefly. When Mr. *Hobbes* had laid this Definition as a Foundation to himself, *A Measure is a Magnitude of a Magnitude, one of another, when it is either Multiple of another, or by Application coincides with it*; and had noted farther that a Line passed over by a Motion, is often called a *Measure* of Time; hence it was easy for him to infer, that a Line sometimes coinciding with Time is therefore equal or unequal to Time; and consequently that a Line and Time obtain a Proportion to one another, the same Way as a Line is proportional to a Line. But if it had come into his Mind, that when a Line is said to be a *Measure* of Time, *Measure* is not strictly taken for the Quantum with which Time is compared according to Quantity

tity (much less for an Aliquot Part, according to its proper Definition), but more loosely for any Notification or Argument of the Quantity agreeing with Time; I say, had he reflected ever so little upon this, he had not so inconsiderately mingled and confounded Things which are as widely distant as the East is from the West. But those Things are to be more thoroughly discussed elsewhere, when we come to treat, according to our Design, concerning *Homogeneous* and *Heterogeneous Quantities*.

In the mean while I will only add one Thing worthy of Animadversion belonging to our Purpose; that *heterogeneous Quantities* are sometimes as the *Measures* of others, because they administer a Kind of Knowledge of *homogeneous Measures*. *Ex. gr.* A proposed Arch of the Equator intercepted between the Horizon and Center of the Sun in the Equator is therefore called the *Measure* of the elapsed Time of the Day, because the Knowledge of its Proportion to the entire Circumference of the Equator argues the Proportion of that Time to the entire Day; *i. e.* is serviceable for its Comparison to the proper *homogeneous Measure*. So also a Line moved over is so far a *Measure* of Velocity, as it denotes the Reason of this Velocity to another before known. Nor is the Case different in other *Measures* improperly so called: from whence that appears sufficiently plain, which was just now insinuated, and which is worth the while to consider, that all the other Acceptations of *Measure* already explained do respect this, or are taken from it.

Moreover *secondly*, *Another Property* of this Kind of *Measure* is, that it has one only certain determinate Quantity, always constant and invariable, *i. e.* it is one and *indivisible* (as *Aristotle* notes

notes in his (*c*) *Metaphysics*), admitting no Difference or Latitude, but having its Quantity immoveable, and as it were constituted in a Point. Otherwise the just Quantity of the Thing measured cannot be estimated by a Comparison with it; but it will still remain uncertain, indeterminate and unknown. Therefore whatsoever is doubtful in its Signification, or variable in its Nature, is so far unfit for a Measure. *Ex. gr.* A *Foot* for the size of a *human Foot*, a *human Palm* or *Cubit*; also a *Mile* taken at large (without putting *German*, *Italian*, or *English* to it) and all such like are not properly speaking *Measures*; because there is a vast deal of difference between the *Palm*, *Cubit* and *Foot* of a *Hercules* with his *Club*, and the *Pygmy* which had a *Reed* for his *Spear*. Nor consequently does he, who mentions the Length of two *Feet*, speak any Thing certain, unless he shew more plainly what *Foot* he means. And he, who says that two *Cities* are a *Mile* asunder, does not express the Quantity of that Distance, unless he respect some of the foregoing *Miles*, or speak more expressly, and sufficiently restrain the Sense of the indeterminate Word. Also if one say that a certain Longitude is equal to the Distance of the *Sun* from the Center of the *Earth*, he says nothing to the Purpose, unless he shew farther what Distance he means, whether the greatest, least, mean, or any fixed and determinate Distance in the Circumference of the solar Orbit. Lastly, if one affirm that a *Right Line* is equal to a *Right Line* drawn from the Center to the *Ambit* of a certain *Ellipsis*; the Dimension of that *Right Line* cannot be computed from hence, because an infinite Number of such *Right Lines* may be so drawn from the Center of

(*c*) *Met. X. 1.*

that

that Ellipsis all different and unequal to one another; and none can know which of these he designs, but by some farther *Determination*. Farther, it is to be noted, that this *Determination of Quantity* is not of one Way only, but admits of some Difference, and therefore the consequent Proportion of the *Measure* will also be something different. For one *Determination* is *natural* and *universal*, and another *particular* and altogether *arbitrary*. That is *naturally* and *universally* determined, which has a determinate Nature, and always respects those Quantities the same Way with which it is compared, or for the measuring of which it is subservient; from whence it is, that it is immediately apt for determining their Proportions in general: and consequently may be also now supposed known itself for notifying their particular Quantities. By which means the Radius of a Circle, and the Side of a Square are determined naturally; the Radius, I say, of a Circle is so determined, because the Subtenses of similar Arches, and all Right Lines placed any how similarly in a Circle, have the same Proportion to Radius, and are so determined in Quantity from a Relation to Radius, that it being particularly determined, their Quantity is always particularly determined at the same Time. As in every Circle (it is no Matter whether it be greater or lesser) the Side of the Hexagon is equal to the Radius, the Right Line of 30 *Degrees* is equal to the half of Radius, and the Chord of 90 *Degrees* is double the Radius in Power: whence if the Quantity of a particular Radius be determined and known (*i. e.* if it be subjected to the Estimation of Sense, or denominated by the Number of some particular known *Measure*) the Quantity of the said Lines may be thence known immediately. In like manner from a known Side of a Square, the Excess of the Diameter

meter above the Side, and the Quantity of other Lines determinately placed within the Square may be easily and certainly known. But it belongs to speculative Geometry to apply this Kind of Determinations, and be conversant about such Dimensions, *viz.* to that Part which does not so immediately investigate the Quantities of particular Magnitudes, as the Reasons of universal ones; from which notwithstanding the Dimensions of Particulars do flow, or are founded in them.

But those Measures are determined arbitrarily, which are applied for the measuring particular Quantities; which, since of themselves they have no Aptitude peculiar to it, are chosen at Pleasure from among infinite others of the same Kind; and are deputed by Compact or Institution for this Office of *Measuring*. Which sort of Determination is obtained by a *Pace*, a *Rod*, a *Furlong*, a *Mile*, and others employed in common Use, which the practical Geometrician assumes for the Dimension of particular Magnitudes. But we must dwell no longer upon Things so evident in themselves.

A *third Property* of *Measure* is, that its Quantity is foreknown. For since (according to *Aristotle's* Definition, *Measure is that whose Quantity is known*) the Reason of *Measure* especially requires it to declare an unknown Quantity, itself must first of all be known. For nothing can be known by that which is unknown, nor illustrated by that which is obscure. But the Knowledge of Quantities is of different Kinds: concerning which,

In the *first* Place, one Kind of *Knowledge* is *radical*, *absolute* and *primary*, whereby the Quantity of a Thing is exposed to the Senses, and immediately discerned and estimated by them, being as it were seen by a Kind of Intuition without further Comparison with other Quantities. By this whatsoever we are able to effect or exhibit in Geometry

is

is accounted known, and that unknown of whose Construction we are ignorant. As if a Circle be proposed to Geometricians, the Side is known of the inscribed regular Trigon, Tetragon, Pentagon, Hexagon, Decagon, Pentecaidecagon, and all that proceed from these in a double Number (or even a Triple, because any assigned Arch or Angle may be bisected by plain common Geometry, and trisected by the Conic Sections) but the Sides of most other regular Figures are more unknown, and scarce can be any Way exhibited scientifically. Moreover the Periphery of a Particular expounded Circle may this Way be said to be known, because its Quantity can be apprehended by Sense, though it cannot be justly compared with a Right Line; and perhaps its exact Proportion to this can never be discovered by us. Notwithstanding, as a Right Line represented to the Sight impresses its Species, and begets a certain Judgment concerning itself, by which it is said to be known: so the Circumference of a Circle leaves the Idea of its Quantity upon the Imagination, according to which it is looked upon as known. Neither perhaps is a Right Line more proper and suitable for measuring the Lines of its own Kind, than the Periphery of a Circle for measuring circular Peripheries, and other Lines which may be referred to them. Again, thus, and no otherwise, are known all the primitive *Measures*, to which *Measures* of the same Kind are referred, whose Quantity can be scarce any Way explained but by pointing the Finger at them and answering him that enquires about their Quantity. *It is as much as you see or perceive by your Sense.* Whence it follows that it is principally required for a Quantity to be estimable by some Sense to make it this way known, and taken for an original Measure; and consequently that it be both subject to Sense, and have a mean Quantity

fo confifting within due Limits, that the Sense may not be easily deceived in its Estimation, *i. e.* that if any thing considerable be added to it or taken from it, it cannot escape the Sense. Wherefore (*d*) *Aristotle* well observes, that the least sensible Magnitudes are most convenient for Measures. Where nothing can be added or taken away but the Difference may be easily perceived and known by Sense, that will be the most accurate Measure. But lesser Quantities are especially such, because the Increments or Decrements of greater Quantities lie more hid from the Judgment of the Sense. That which is taken from, or added to, a Furlong, Talent, or universally any greater Measure may be more hid, than that which is taken from, or added to, a Foot, an Obolus, or lesser Measure. From whence the Philosopher concludes, That all Men make that especially a Measure, from which nothing can be deducted, as to the Judgment of Sense, and think they know a Quantity then, when they know it by such a Measure. Therefore are all great Magnitudes quite excluded from such an original Measure, as unfit for it; because their Differences can either not at all, or not exactly enough be judged of by the Sense. For as Opticians observe, the Distances exceeding two hundred Foot cannot be judged by Sight, the Sense which reaches beyond all others, but they all seem equal to one another; thus the Sun, Moon, and fixed Stars, though some be really removed from us so many Myriads of Miles farther than others, yet they all seem to have the same Distance, and be placed in the Perimeter of a Sphere having its Center as it were, in the Eye of every one: And even the Differences of those Longitudes, which come nigher the said Intervals are hardly computed by

(2) Met. X. 1.

the

the Sense: From whence it also comes to pass that (by Reason of the true Differences, not rightly attended to, of the visual Rays proceeding farther) an objected Plane either of Land or Sea, seems to arise or swell into a gibbous Surface. But of this sensible Knowledge too much.

Secondly, Quantity is known from a Comparison with any *Measure* judged by Sense in a Way expounded; *viz.* when it is known what Relation in Quantity it has to that *Measure*, how often it contains, or is contained in it, how much it exceeds or falls short of it. This Way known Quantities are said to be *mediate* or *secondary Measures*. Magnitudes, I say, no where objected to the Senses, nor any Way estimable by them, may sustain the Reason of a *Measure*, if their Proportion to other Magnitudes already estimated by Sense shall be found by an *Organical Mensuration*, or any lawful Ratiocination. *Ex. gr.* The Semi-diameter of the Earth although seen to no Body, and beyond the Estimation of Sense, may yet be the *Measure* of the Magnitudes and Distances of the heavenly Bodies; if it be known by proper Hypotheses, and a just Discursus how many *Furlongs, Paces, or Feet* it contains, or is equal to; or if it be so to some of those *Primitive Measures* before known, as such an expounded Right Line is to another Right Line exhibited.

But *thirdly*, that is said to be known by a peculiar Reason, which is expressed in Numbers denoting its Relation to some expounded Quantity before estimated (whether it be especially known to us by familiar Use, or be assumed *gratis* and at Pleasure); if that before known Quantity be conceived, either as undivided (*i. e.* designed by Unity, or distributed into equal Parts, and denominated according to that Division by a certain determinate Number, and then it be found what

Number of those equal Parts, or how many of those Units, or what Part of that Unit agrees with the Quantity proposed ; that Quantity will be said from thence to be perfectly known, *i. e.* known in the Parts of the given *Measure*. Moreover oftentimes a Quantity otherwise expounded to the Senses and estimable by them (*i. e.* whose Reason to an expounded Measure may be estimated by sensible Limits) is nevertheless reckoned unknown, till its Proportion is reduced into Numbers, or explained by Numbers according to some stated *Measure*. *Ex. gr.* Although the Right Sine of 30 *Degrees* among others be drawn in a Circle and offered to the Eye, yet its Quantity will be reckoned partly unknown, till by Consideration or Argument it be discovered equal to half the Radius ; and then its Quantity will be esteemed perfectly known. That Things are accounted unknown, whose Reason in Numbers to some *customary* and *usual Measure* is unknown, seems to proceed from many Causes : *As first*, because the Judgment of Sense is more slippery, and uncertain, and less sagacious and exact than an Estimation of Quantity founded in the certain Proportion of Numbers. *Secondly*, Because Quantities, or the Reasons of Quantities, are more easily and conveniently exhibited by the Symbols of Numbers represented in the Mind than really by the Senses. *Thirdly*, Because the sensible Species of an Object is more vanishing, unconstant, and mutable, than Number, which is easily retained in the Memory, and committed to Writing, and is obnoxious to almost no Changes by Increase or Decrease. And *fourthly*, because the Quantities of all Things are reduced by the Intervention of Numbers to a few very *familiar Measures*, which are established by common Consent. Which Causes (and whatsoever more there may be) of this Thing, (*viz.* why that

that is accounted as especially known, and perfectly discovered, whose Reason is expressed in Numbers to something before known), though not unworthy our Consideration, I now pass by in order to hasten to something else. So far I have touched upon the particular Knowledge of Quantities: But

Fourthly, Every Quantity is said to be after a Sort known and determined (as we have said above) whose general Nature we comprehend, though we are ignorant of its particular Quantity, or do not consider it. Thus we know how a Radius is affected in a Circle, or a Side in a Square, though we are ignorant, or neglect the Quantity of this or that particular Radius of a Circle, or Side of a Square. Especially those Quantities are known which are laid down for the Generation of others, and consequently determine every Thing following that Generation, and from thence naturally challenge the Place of a Measure. As if a Circle be supposed to be generated from the Revolution of its Radius, a Square from the drawing of its Side into itself, or from its direct parallel Motion; then because the Quantity and Position of all other Lines in a Circle or a Square depend upon the Quantity of the Radius of the one or Side of the other with such a Motion; consequently those are not undeservedly reckoned as primarily known: and are general primitive Measures, from a Comparison with which, the Things which obtain a similar Situation perpetually determinate in respect of them, are consequently known by a *General Method*; *i. e.* the constant Proportion may be known of these to those, and therefore the particular Quantity of these may be also known, from a Supposition that the particular Quantity of those is known. For, if the Proportion of two Quantities be found, the

one will be known from the Knowledge of the other.

Hitherto concerning the Properties of *Measure*; it now follows, according to our proposed Method, that we add a few Things concerning the *Ways* of *Measuring*. Those are various, but we will just glance at some of the most principal that offer themselves to our Thoughts. *Homogeneous Quantities* then however unknown and indeterminate are compared together (or measured) with such as are known and determinate.

First, By seeking their Proportion by pure Reasoning. Thus from a given Radius the Geometrician gathers the Quantity of the Side of an inscribed regular Trigon, by demonstrating from its own Principles that it is triple the Radius in Power. So also from the Foreknowledge of the apparent Diameter and true Distance of the Moon from the Eye, by help of the Canon of Sines constructed from geometrical Reasonings, may be shewn the Quantity of its true Diameter. This Method is altogether theoretical, whereby the general Dimension of Quantities is performed, which Reason only can attain; and consequently is strictly perfect and exact.

Secondly, By organical Dimension alone, which serves for applying the Quantities of unknown Things to the Numbers of a determinate Measure; especially those Quantities which cannot be estimated by Sense, at least not commodiously and accurately. Thus we measure Arches and Angles by circular Quadrants distributed into Degrees and Minutes, and Longitudes by Rules and Scales divided into equal Particles. This Method is only employed about particular Quantities, and is purely mechanical, and therefore never strictly precise and accurate.

The *third Method* is by Reasoning and organical Dimension conjunctly, by the Labour of the Mind and Mechanism of the Hand. Which indeed is practical and conversant about Particulars, yet so as to need the help of general Theorems, whence it is lame on one Leg, but walks direct and certain with the other ; which, as it applies the Rules of Geometry, has a certain Divinity and Participation of eternal and indefectible Truth, but as it requires mechanical Labour is fallible, mutable, and obnoxious to Mistakes and Errors. By this Method we not only measure all Things that are placed within the Reach of our Sight or Feeling, but also innumerable Things inaccessible to our Senses, and hardly to be comprehended by the Mind ; such as the Profundity and Circumference of the Earth, the Magnitudes and Interfices of the Stars, and whatsoever has any Proportion sensibly finite with Quantities subject to an organical Dimension or instrumental Mensuration. For from the Proportion of the Things mechanically measured to others exceeding that Dimension, we may also infallibly discover the Quantity of these by help of Geometry.

Fourthly, To these I subjoin the Method by which we answer such as enquire after the Quantity of a Magnitude by really exhibiting it to the Senses to be estimated or to be reduced to the Numbers of any known *Measure* by the said mechanical Dimension. As if one ask the Quantity of a Right Line touching a proposed Circle from a given Point. The Question will be satisfied in part by drawing that Right Line geometrically, and shewing it to the Eyes of the Querent. For thus he will either discern its Quantity by looking upon it, or find to how many Particles of a known Measure it is precisely or nearly equal, by examining it according to some Scale.

The *fifth* Method is that whereby an unknown Quantity may be declared by some Equation, which expresses its Relation to other known Quantities, and consequently offers it to the Mind to be comprehended; the artificial Resolution of which Equation according to certain Rules accommodated for that purpose, and prescribed in the Doctrine of *Analytiks*, will entirely perform this Dimension, and discover the Quantity sought either Geometrically or Arithmetically. Thus if there be given the Radius of a Circle, and Tangent of an assigned Arch, and the Quantity of the Tangent of the double Arch be sought, putting r for Radius, a for the given Tangent, and x for the Tangent sought, the Quantity sought will be represented by this Equation: $xrr - xaa = 2rra$; or $rr - aa : 2rr :: a : x$, *i. e.* The Tangent of the double Arch sought, being drawn into the Difference between the Squares of the Radius and the known Tangent of the single Arch, is equal to twice the Square of the Radius drawn into the Tangent of the single Arch. Or which comes to the same, by this Analogy: The Difference between the Square of the Radius and the Square of the given Tangent will be in proportion to twice the Square of the Radius, as the given Tangent is to the Tangent sought. By which Theorem the most excellent *D. Pell* refuted the Quadrature of *Longomontanus*. Also if the Subtense of any Arch be given in Numbers, and Unity put for the Radius of the Circle, and the Quantity be sought of the Subtense of the triple Arch: putting z for the given Subtense, and q for the Subtense sought, the sought Quantity will be declared by this Equation: $q = 3z - z^3$; or $qr^2 = 3zr^2 - z^3$. *i. e.* The required Subtense of the triple Arch will equal thrice the Subtense of the given subtriple Arch less the Cube of the said Arch. Which Theorem may be useful for
the

the same Purpose. But we will not dwell upon explicating those Things any farther.

Yet I beg your Patience a little, while I am lightly touching upon the other principal Notion of *Measure*, that I may not trouble you again during the little Remainder of this Term : But if I seem more prolix than is fitting or customary, I would have you to interpret it, as proceeding from my exceeding Unwillingness to be torn from your Presence and Society, and so soon to bid you Farewell. The other principal Acceptation of Measure according to which it always designs in the Elements that which being some Number of Times taken exactly composes and constitutes or some Number of Times taken away destroys and quite exhausts the homogeneous Thing measured, has already been abundantly described in the preceding Lecture. As to which, the *Mensurability* here meant does also agree with all Quantities whatsoever ; for every Quantity (Magnitude originally and simply, but all the rest secondarily, and consequentially) is its proper Way *mensurable* according to this Notion, *i. e.* is divisible into any Number of equal Parts or Degrees ; or is denominable, representable, or explicable by any Number : as the *Radius* of a Circle however small is supposed by Trigonometricians to be divided into a hundred thousand, or a thousand thousand, or as many more as you please of equal Particles ; and any Time however short may be divided into any Number of minute Parts according to the Will of the Computant ; also as many Degrees of any Velocity or Weight may be supposed as any one shall think convenient : For every Number is a fit Symbol of every Quantity, and capable to signify it : and as every mathematical Number, consisting of equal Units, is composed of Unity so often taken, and exhausted by Unity so often taken away, *i. e.* is exquisitely divided
and

and measured by it ; so correspondently the Quantity expressed by any Number (*i. e.* according to the Exigence of that Number distributed into so many Particles, answering to Unity) is measured by any Particle which is designed by Unity.

Here seems to be nothing of Difficulty or Obscurity : and the Quantities compared with respect to such a *Measure* are by Geometricians wont to be called *Symmetrous* or *Affymmetrous*, *i. e.* *Commensurable* or *Incommensurable*, and scarce any Thing in the Mathematics is more wonderful or more useful than the Contemplation of those Properties, though nothing more remote from a vulgar Capacity and Conception. *Aristotle* observes, in an Instance taken hence, how much the Admiration of the unskilful Multitude does differ and oppose the Opinion of learned and knowing Men ; for the *Affymmetry* or *Incommensurability* of the Diameter of a Square with its Side is reckoned among those Things, which the Vulgar do especially wonder at. *It (a) seems wonderful to all that a great Thing cannot be exhausted by any very small measure of another homogeneous Quantity ; but on the contrary, a Geometrician would wonder at nothing more than if this did not happen. Plato* pathetically laments the common Ignorance of this Property, which he also calls a *ridiculous and shameful Ignorance resting in the Minds of most Men* : And he seems to say that the Want of this Perception is not so much human as brutish. *I have wondered, says (b) he, at our Affection about these Things, and to me it seems not to be human, but rather an Affection of brute Beasts.* Therefore he professes himself ashamed for the Sake of all his Countrymen, because most of them were ignorant of so obvious a Property of Quantities ; and being rather carried away with

(a) Met. I. 2.

(b) Plato VII, de Leg. versùs Finem.

a contrary

a contrary Errour thought all Magnitudes of the same Kind to be *commensurable*. *I am ashamed*, says he, *not for my self only, but also for all Grecians, &c.* Let us then take up a little Time in contemplating this wonderful Property.

As to *Symmetry* or *Commensurability*, with the vulgar and foreign Writers it sometimes denotes a due Quantity of any Thing constituted within determinate Bounds, agreeable to its Nature. Thus *Aristotle* (c) in his *Ethics*. *An over plentiful* (says he) *as well as over sparing Quantity of Drinkables and Eatables do equally injure and destroy the Health, but a commensurable Share does help, increase and preserve it.* Where *Commensurable* does signify moderate, convenient, neither exceeding nor falling short of its due Quantity. Also *Plato* in his *Politics* says, *secondly, concerning what is commensurate and beautiful and perfect and convenient.* Where *Commensurate* is of kin to *Beautiful*, *Perfect*, and *Convenient*, which shew how it is taken. But the *Symmetry* of a Thing composed of various Parts does more often design a *decorous* and *apt Agreement* or *Conformity* in the Parts to one another, in which the *Beauty* and *Elegance* of Things does principally consist: wherefore such a *Symmetry* is chiefly considered in *Architecture*, and is thus defined by *Vitruvius* (d), *Symmetry is a convenient Consent from the Members of the Work itself, and from the Parts separated to the Appearance of the whole Figure, answerable to a Part supposed.* According to which Acceptations, it plainly appears on the contrary what is *Assymetry* or *Incommensurability*, viz. an *enormous, disproportionate, disagreeable, excessive, or defective Quantity of a Thing.* But passing by those vulgar Acceptations,

(c) Eth. II. 2.

(d) Vitruv. I. 2.

Secondly,

Secondly, *Symmetry* or *Commensurability* does sometimes denote any *Comparability together*, as to *Quantity*, of *Magnitudes*, or other *Quantities*; so that according to the other more extensive Acceptation of the Word *Measure* this signifies to compare the *Quantities of Things together*, or to investigate the *Proportion of an unknown Quantity to a known one*. In which sense *Symmetrous* is all one with *Homogeneous*; and *Affymmetrous* with *Heterogeneous*; as far as all *Quantities* of the same *Kind* are proportional to one another, and consequently are this Way *commensurable*; but *Quantities* of a different *Kind* have no *Proportion* to one another, and consequently can be no Way *commensurate*. Thus all *Lines* are *symmetrous* to one another, but a *Line* in respect of a *Superfice*, a *Body*, *Time*, *Velocity*, or *Weight* is *affymmetrous*.

But commonly among *Geometricians* those *Quantities* are more strictly called *commensurable*, which may be measured by the same homogeneous *Quantity*, *i. e.* perfectly divided so as to have no *Remainder*, and are quite exhausted by a continued *Subtraction* of it: or the same *Quantity* of which is an aliquot *Part* of both: or which is as one *Number* to another of that *Kind*, ascribing *Unity* to *Numbers*. Thus an *Inch*, a *Foot*, and a *Pace*, are *commensurate Lines*, because an *Inch* taken once makes itself, taken twelve *Times* makes a *Foot*, and sixty *Times* a *Pace*: or because those *Longitudes* are to one another as the *Numbers* 1, 12, 60. So also in *Money* a *Mark* and a *Pound* are *commensurate* because a *Groat* (or the third *Part* of a *Shilling*) measures both, *viz.* taken forty *Times* it makes a *Mark*, and sixty *Times* a *Pound*, or because they are to one another as 2 and 3. In *Times*, the *Cycle* of the *Sun* is *commensurate* with the *Cycle* of the *Moon*, because the former is to the latter

latter as 28 to 19, and one Year measures both. But these Things are plain enough.

Those Quantities are *Incommensurate* of which no common *Measure*, though ever so small, can at all be found; there being none such in the Nature of Things, which can compleatly divide both without a Remainder, or which may have any Proportion explicable by Numbers integer or fracted: consequently if one of them be expressed by any Number, the other will be entirely inexplicable. A most famous and notorious Example of which Affection is that of the Side and Diameter of a Square, which are so affected together that no Line, though ever so small, can measure both. But if the thousand thousandth Part of one, *ex. gr.* the Side be applied to the Diameter, or taken from it, as often as it can, there will always something remain, and the Congruity or Division can never be compleat. And this is that wonderful Property which almost exceeds human Capacity, and so puzzles such as are unaccustomed with these Things; which perhaps will yet seem more wonderful, if we consider the Observations we shall subjoin.

First, That, if two *incommensurable* Quantities A and B be proposed, a Quantity may be found commensurable, *ex. gr.* to A in any Proximity to B, or whose Difference from B is less than any assignable Quantity; which may easily be demonstrated and inferred (if I remember well) from a Lemma demonstrated in the third Book of *Theodosius's Spherics*: From whence it appears that that, whatsoever it be, from which this (e) *Incommensurability* arises, and by which an *Incommensurable* Quantity exceeds or falls short of another *Commensurable* one by a Quantity expounded will be

(e) Vide Cavall. Exerc. p. 526.

infinitely

infinitely little, *i. e.* less than any Quantity assignable or comprehensible to the Mind: Which is also equally manifest from the Extraction of the Roots of such Numbers as are called *Irrational*: For there an Approach is always made nearer and nearer the true Value of the Root sought, and yet the just Value can never be obtained.

Secondly, and especially, That Quantities are not only simply *incommensurable* but also seem to admit many (perhaps infinite) Degrees of *Incommensurability*; so that one Quantity in respect of any Quantity expounded may be farther removed from *Commensurability* than another, and another than this, and so on, till we come to some extreme, which is infinitely distant from the first. *Euclid* has observed that certain Lines are *incommensurable* to any Line expounded not only in Length, but, which is more, even in Power: and also that the Biquadrates of some Lines are *incommensurable* to the Biquadrate of a Line expounded, and respectively all the Superior Powers of these to the coordinate Powers of that. Therefore if a Power denominated by a Number at an infinite Distance from Unity be *incommensurable* to an expounded Power respectively coordinate, the former seems to have infinite Degrees of *Incommensurability* with respect to the latter. And thus the Circumference of a Circle seems to be with Respect to the Radius. For the Side of the inscribed Square is *incommensurable* to the Radius in Length, and consequently the Archa of the Square is *incommensurable* to the Radius. Also the Square of the inscribed Octagon is *incommensurable* to the Square of the Radius, and consequently the Square of the Octagonal Perimeter is *incommensurable* to the Square of Radius. And thus the Archs of all *regular Polygons* inscribed in a Circle have their superior Powers *incommensurate* with the coordinate Powers of *Radius*; from whence

the last of these *Polygons*, *i. e.* the Circle itself does seem to have its Perimeter infinitely *incommensurable* with the *Radius*. Which if true, will put a final End to the *Quadrature* of the Circle, since the *Proportion* of the *Circumference* to the *Radius* is thence altogether *inexplicable* from the Nature of the Thing, and consequently that Problem, requiring the Explication of such a Proportion, is impossible to be solved; or rather it requires that for its Solution, which is impossible to be apprehended. For a Problem is resolved in two Points, *viz.* either by shewing what it is, and how that may be done, which is required; or by discovering that it cannot be done. But this great Mystery cannot be explained in a few Words; if Time and Opportunity had permitted, I would have endeavoured to produce many Things for the Explication and Confirmation of this Conjecture.

Lastly, not to be any longer tedious, I would only admonish you farther, that the principal Reason of *Incommensurability* seems to be founded in this, that since a *Mean Proportional Number* may always be found between two plane similar Numbers (*i. e.* between such as are generated from the Multiplication of *proportional Numbers*) because the Product made by the Multiplication of plane similar Numbers is always a Square Number, whose Root is that *Mean Proportional*; also between two similar solid Numbers there always lie two *Mean Proportionals*: And by a like Reason between two similar Plano-plane Numbers are three *Mean Proportionals*, and so on continually as to all other imaginary Dimensions beyond; since I say, Things are thus in similar Numbers, and it is demonstrated in the *Elements*, that it happens quite otherwise in all dissimilar Numbers; (for on the Part of the Thing there is no *Mean Proportional Number* between two dissimilar plane Numbers, nor between

between two dissimilar solid Numbers, nor between two dissimilar Plano-plane Numbers, and so on, which is also there shewn;) hence, if two Quantities are supposed to be to one another in the Reason of two plane dissimilar Numbers, and a *Mean Proportional* be found between those Quantities, which may perpetually be done, because of the indefinite Divisibility of every Quantity, there will be no Number in universal Nature which can represent or answer to this Quantity, and consequently, those being supposed and expressed by Numbers, this will be *incommensurable*. By the same Argument, if two *Mean Proportional* Quantities be found between two Quantities expressed by dissimilar solid Numbers (which the Nature of the Thing will permit to be done) the whole Series of Numbers, how great soever it be, will afford no Number capable of representing them; and consequently these, in respect of the Quantities expounded, will be altogether *ineffable* and *incommensurable*.

From whence it appears by the Way, how much more infinitely narrow, and as it were poor, the *Nature* of *Numbers* is, than of all other Quantities; for comparatively speaking, *rational* or *common Numbers* do suffice for expressing but very few Quantities: and both the Sides and Areas of most regular Figures are no otherwise to be exhibited and explicated than by *Surds* and *irrational Numbers*. But we can only now hint at these Things cursorily and in Haste, which require a larger Explication.

Nothing now remains, but that I return my due Acknowledgments of Gratitude to you, my most judicious and courteous Auditors, for your great Patience and kind Indulgence of these Things of less Consequence during the whole Course of this long Term. I wish what is to come may be
more

more worthy your so benign and candid Attention, and more acceptable to your Desires ; that it may more delight your ingenious Curiosity, and set a greater Edge upon our own poor Industry. In the mean Time I bid, I heartily wish you farewell, and so recommend you to the good God.

The Lectures hitherto are writ as they were read publickly, the Order being no where interrupted ; I now break the Series. For since I am neither obliged, nor able to exhibit all in fewer than ten Lectures at least, by Reason of the Greatness of the Labour and Want of Time ; I have purposed to annex the three last to some few yet remaining.

LECTURE XVI.

*Of the Homogeneity and Heterogeneity of
Quantities.*

MOST learned Auditors, I am glad to find you in Health, and wish you a long Continuance of it, and without further Preface apply to my Task, proceeding in my former Method. I suppose you remember we proposed to treat of the *General Affections* of Magnitudes, and of other Quantities from thence. A few of which having already diligently enquired into, as well as I am able, I have now reached nigh the very Soul of the Mathematics, *viz.* to *Proportionality*, on which almost every Thing depends in the Mathematics which is wonderful and abstruse. But since *Proportionality* consists in the Comparison of Proportions, and Proportion in the Comparison of Quantities, it seems expedient by way of Preparation to consider the *Comparability* of Quantities, especially that which is requisite to *Proportion*. For all Quantities cannot be so compared together, as to be said to have a *mutual Proportion*, but only these that more nearly touch one another in a pecu-

liar Respect, for which Cause they are wont to be called *Homogeneous*.

We come now therefore to treat of the *Homogeneity* and *Heterogeneity* of Quantities. And it is here first to be noted, that besides the common Attributes, which agree with all Quantities distinguishing them from what is void of Quantity (*viz.* all Kinds of *Extension, Divisibility, Mensurability, and the like Affections,*) there are other Differences which distinguish Quantities from one another, and distribute them into subordinate *Genera* or *Kinds*; so that all those Quantities which are contained under one of those *Kinds* are called *Homogeneous*, and those under different *Kinds* *Heterogeneous*. Which subordinate *Kinds* of Quantities disposed as so many *Classes* and *Predicaments* of Quantity, almost the same way under Quantity as the common *Predicaments* under *Entity*; are very different from one another, having nothing common or similar beside the general *Affections* of Quantity: But the Agreement and general Reason of the Diversity of these is the Aptitude or Ineptitude, Capacity or Incapacity of Quantities to a Composition or Coalition into some Whole, or to a Subtraction or Constitution of a new Remainder: or, if I may so speak, it is the Addibility or Inaddibility of one Quantity to another, the Subducibility or Non-subducibility of one from another: or it is the comprehensibly certain Excess of one above the other, or Defect of one below the other; or it is the Incapacity of such an Excess or Defect, and hence of the Equality or Inequality of one with Respect to the other: In these Things, I say, with their Concomitants or Consequents is founded the Reason of *Homogeneity* and *Heterogeneity* respectively. For of the Things which are so affected, that they may be Parts of one Quantity conceivable by itself, that they may be gathered into one Sum, augment
ment

ment one another by Addition, or diminish by Substraction, differ from one another by a certain Excess or Defect, and may be properly and fitly said one to be equal to, greater, or lesser, than another, these are *Homogeneous* pertaining to the same Classes of Quantities comparable to one another: And what are otherwise are *Heterogeneous*, and to be referred to different and unlike Tribes. But if we pursue farther into the Original of this Diversity, and examine whence such an *Incomparability* of Quantities does arise; we will find it to proceed nearly from these Causes.

First, from the very different Nature of certain Quantities, by which it happens that they cannot be subject to one *common Measure*, that may equally agree with both; nay, the Mind itself can no way connect or conceive them as one determinate uniform Compound; nor any way compare them together according to Equality or Inequality, Excess or Defect. Thus *ex. gr.* Magnitude, Weight, Velocity, Time, Resistance, and Force are *Heterogeneous* and not to be compared together, because they are so different in Nature that they measure nothing in common, nor can any of them be connected together, be congruous, or enter any Compound not very deformed and chimerical; they cannot be adequate, exceed or fall short of one another, or any way be conceived to affect one another in Respect of their Quantity. For who can understand what is the Sum of two Years added to three Miles; or how much three Ounces of Weight exceeds two Minutes of Time; or what remains after the Deduction of four Degrees of Velocity from three Cylinders? No more can any Number of Musical Tones be equal to so many Rays of Light, or the same Number of Smells to so many Colours. Their huge Dissimilitude and Distance of Nature hinders them from being any intelligible

Way referred to one another according to Quantity. The Quantity of Magnitude is continued, simultaneous, absolute, and obvious to the Senses: The Quantity of Time, vanishing, successive, imaginable only in the Mind, consequent and significative of Motion: The Quantity of Velocity depends upon the conjunct Reasons of Time and Space: Weight, Force, and Resistance imply certain Actions and are estimated from certain Affections: so dissonant are these to one another that they cannot possibly be conjoined into one. This is the first and principal Cause of *Heterogeneity*.

A *second Reason* of this Difference is fetched from the various Degrees of Perfection as to Quantity; as some Quantities are extended and may be divided more ways than others, so that these are scarce Quantities in Respect of those, and consequently cannot be compared with them according to Quantity. Thus a Superfice is more ways divisible than a Line, and a Body than a Superfice, nor is a Line any otherwise to a Superfice, and a Superfice to a Body, than a Point to a Line, *i. e.* than an Indivisible to a Divisible, or a Non-Quantity to a Quantity: For a Line is Nothing in Respect of a Superfice but as it were a long Point; and a Superfice is nothing in Respect of a Body but a broad Line, or a long broad Point. Therefore a Line, a Superfice, and a Body are not to be referred to one another, and consequently are *Heterogeneous*. For thence it comes to pass, that these cannot be compared together according to Equality or Inequality, nor so compounded as to make any Sum, nor one subtracted from another so as to have any Difference resulting, *i. e.* being added they can beget no Encrease, nor deducted Decrease. The same Reason holds of Instants in respect of Time; of the Degrees of an encreasing Velocity which are acquired in particular Instants
in

in Respect of the whole Velocity ; and of Momentary Conatus's in respect of Motion, Weight, and Power.

A third Origin yet of this Diversity is an indefinite and incomprehensible Respect of one Quantity to another, such as between Things finite and infinite, or Things otherwise cognate in Name and Nature. From whence a finite Right Line and an infinite one are accounted of different Kinds, though in an infinite Right Line may be found every finite one, and that may be esteemed as constituted of this infinitely repeated. Hence that celebrated Principle of (a) *Aristotle*, that there is no *Proportion of a finite to an infinite* : The Truth of which Sentence or Axiom the Sagacity of modern Geometricians seem in part to have broken ; while they demonstrate a just Proportion and even Equality it self of innumerable Planes and Solids produced *ad infinitum* with other finite Planes and Solids : which Prodigy that famous Geometrician *Torricellius* did first of all exhibit. From whence it appears that infinite Magnitudes are sometimes *Homogeneous* with finite ones, since they are sometimes equal to these, and sometimes fall short of them. Or from hence rather it may be inferred, that every Thing without Limits is not infinite in Quantity ; or yet more plainly, that the Infinity of a Surface or Body does not always follow from an Infinity of one Dimension. The Reason of which seems not very difficult ; for it happens because the infinite Diminution of one Dimension recompenses the infinite Augmentation of the other. It is not therefore so much beyond Belief for a finite Magnitude however small to be extended in Length *ad infinitum*. Therefore that it may hold universally, the before noted Axiom ought to be thus explained :

(a) De Cælo I. 6.

There is no Proportion of a Thing finite in Magnitude or Quantity to a Thing infinite in Magnitude or Quantity of the same Genus. But we are not to understand in general, that there is no Reason between a limited Figure and an unlimited Magnitude. From these Roots springs the *Heterogeneity* of Quantities, and those Things which on the contrary agree together, which by Nature are not so dissimilar, nor constituted in a different Degree of Quantity, nor infinitely severed from one another, those, I say, are *Homogeneous*.

But *Euclid* in the Definitions of his fifth Book defines *Homogeneous* Quantities to be these, one of which (*viz.* the lesser) being some Number of Times taken or multiplied may exceed the other. The third Definition of that Book is such : *Reason is a certain Habitude of two Magnitudes Homogeneous to each other, according to Quantity.* And, lest any one should doubt what he understands by *Homogeneous* Magnitudes, he subjoins ; *Magnitudes are said to have a Reason to one another when one being multiplied is capable to exceed the other.* Where our *Element Compiler* (as a most learned and famous Man in my Opinion rightly observes, in his Disputation against *Meibomius*) delivers not these (as others beside *Meibomius* expound, and, which I wonder at, the sagacious *Clavius* seems to encline to, though elsewhere he speaks differently) to shew what *Homogeneous* Magnitudes have a Reason to one another, as if some had none ; but rather, what Magnitudes are *Homogeneous*, lest any should be deceived or held in Suspense with the Obscurity of that Word in the foregoing Definition. For when he there defines *Proportion to be the Relation or Habitude of Homogeneous Magnitudes*, indefinitely speaking, he sufficiently intimates, that he understands *Homogeneous Magnitudes* universally, and not only certain particular Magnitudes ; otherwise,

if he had not thought that all *Homogeneous Quantities* are *mutually proportional*, it would have been out of the Way for him to insert them in his Definition as the Subject of *Proportion*; and it would have been more right for him to have excluded those, and put some adequate Subject in their Place. He will therefore have all *Homogeneous Quantities* to be affected with *Proportion*, to one another; therefore two Lines, one finite and the other infinite, (though Lines do in general agree,) are not *Homogeneous* in *Euclid's* Opinion; because a finite Line, how often soever taken, will never exceed an infinite One; and the same happens in every finite Respect of every other Thing infinite in Quantity (I say in Quantity not local Extension, as was before insinuated;) and in like manner it plainly appears that Points, Lines, Superficies and Bodies are *Homogeneous*; seeing that innumerable Myriads of Points cannot exceed one of the smallest Lines, nor a Million Million Superficies transcend one of the most minute Corpuscles. So also *plane cornicular Angles* or *Angles of Contact*, if they be Angles, or any kind of Quantity (each of which Assertions is doubted and denied by famous Mathematicians, concerning which I determine nothing at present) I say, if these *cornicular Divergences* which are made by the meeting of Right Lines with Curves, be truly Angles, and endowed with Quantity, at least they will not be *Homogeneous* with rectilinear Angles, because every the least and the most acute rectilinear Angle infinitely exceeds an innumerable Number of these Cornicular ones: As *Euclid* has demonstrated concerning the *Angle of Contact* made by a Tangent with the Periphery of a Circle; *Apollonius*, concerning those made between Tangents and the Conic Sections; and (b) *Archi-*

(b) *At least it follows from his Demonstrations.*

medes,

medes, concerning those made between a spiral with its Tangent ; and our selves may do the same, by one only universal Demonstration fetched from a Composition of Motions, concerning all Curve Lines bended towards the same Parts ; so that those Angles of Contact are no otherwise to rectilinear Angles, than a Point to a Line, or a Line to a Surface.

But all *finite Lines* however dissimilar are *homogeneous* to one another, not only Right Lines to Right Lines, but Curve Lines to Right Lines, and all Curve Lines to one another ; though as far as it does not appear concerning the determinate Proportions of most Curve Lines to Right Lines as of the Circumference of a Circle or Elipsis to some Diameter, it may be doubtful what is the Proportion between them ; because *ex. gr.* the Diameter of a Circle taken four times exceeds the Circumference. Moreover the present Age has this to glory in, that the *Proportion* of certain Curve Lines to Right Lines is now discovered with admirable Subtilty, and plainly demonstrated ; which was thought by former Geometricians impossible to be investigated. In like manner all *finite Superficies* are Homogeneous, even Planes with Curve Superficies, because the Proportion of these to those is not only possible but easy to be demonstrated ; as it is shewn by *Archimedes* to what circular plane Area the curve Superfice of a right Cone, a right Cylinder, a Sphere or any Portion of a Sphere is equal. And the same Way are all *finite Solids homogeneous*. Nay, if Angles are at all Quantities and partipate of Equality or Proportion (which as we have said is doubtful) even rectilinear Angles will be *homogeneous* to some curvilinear ones, in this Sense, because some of these are demonstrated equal to some of those, *viz.* by *Proclus* in his *third Book* at the *twelfth Axiom*. However all rectilinear Angles are
homogeneous

homogeneous to one another. These Things seemed so manifest to *Archimedes*, that he doubted not to assume this for a Truth that *Every determinate Magnitude may be as many Ways added to itself, or multiplied, as to exceed any other Magnitude of the same Classis.* To which *Clavius* premises a like Postulate in the *tenth Element.* *Let it be required that every Magnitude may be so often multiplied, till it may exceed any Magnitude of the same Kind.* Nor is it less manifest that all *finite Times* are *homogeneous*, because the shortest Space of Duration being often repeated will exceed the longest Interval less than Eternity. Also all *Velocities* are *homogeneous*, for the slowest Degree of *Velocity*, being often enough repeated, will transcend the most rapid *Velocity* of the *Primum Mobile.* But an *infinite Velocity* seems inconsistent; for a moveable Body endowed with such a *Velocity* would measure any Distance in one Instant, and consequently would possess more Places than one at the same Time, *i. e.* would be congruous to a Space exceeding itself, how great soever it be, which seems impossible. Again all *Numbers* are *homogeneous* to one another, as they are all fit to represent Magnitudes of the same Kind; even such as may be accounted *heterogeneous*, as they are applied for expressing Quantities of a different Kind; nay every Number however *heterogeneous* it be to itself, as the same does represent *heterogeneous* Quantities; for there is no Number which may not be Linear, Plane, Solid, Plano-plane, Plano-solid, Solido-solid, or be conceived under all Dimensions whatsoever, whether natural or fictitious, at the Pleasure of the Computant. Lastly all *Weights*, are *homogeneous*, assigning Gravity to solid Bodies only, as in reality it only is in Physics; For if Gravity be attributed like Magnitude to Lines and Superficies, as Geometricians suppose, when they investigate the Centers of Gravity

Gravity to a Triangle, Parallelogram, plane Parabola, and other plane Figures; also to the Surface of a Sphere, Cone, Cylinder, and other curve Superficies; and to all Lines whether curved or compounded Right Lines; this, I say, being supposed, all *Weights* are not *homogeneous*, but only these that are of Magnitudes of the same Kinds. Whence (c) *Aristotle* seems to reprehend *Plato* not undeservedly, because, in his *Timæus*, he imputes the Differences or Excesses of Bodies in Gravity to a Multitude of Superficies. For how many soever the Gravities may be of Superficies, they cannot constitute or be encreased to the Gravity of an aggregate Body, since they are of a different Kind, and therefore are unsuitable. Nor indeed have all these Things any other Tendency but to instruct us what *Quantums* may be compared together as to *Quantity*; for there is no Fault greater in *Geometry* than to seek or assert the Proportion of *Heterogeneous* Quantities to one another. As if one enquire how many Right Lines are equal to such a Square, how many circular Peripheries do make such a Circle, how many Squares such a Cube, or how many Times such a Space or Weight. From whence *Vieta* that great Master of *Analytiks* prescribed this Law to be first observed in all analytical Disquisitions. (d) *Let that be the first and perpetual Law of Equalities or Proportions, which because it is conceived of Homogeneals, is called the Law of Homogeneals, and is this, that Homogeneals are compared with Homogeneals (i. e. exclusively with them only.)* (e) *For (as he goes on) those Things which are heterogeneous, it cannot be conceived how they can be affected one with another, as said Adrastus.*

It is true that such Expressions do often occur with those that apply the excellent Method of Indi-

(c) De Cælo III. 1. (d) *Isag.* cap. III. (e) Cap. xix. visibiles

visibles to the Solution of Problems or Demonstration of Theorems: All those parallel Lines are equal to such a Plane, the Sum of those parallel Planes constitutes such a Solid; but they explain their Meaning, and say that they understand nothing by Lines, but Parallelograms of a very small, and (pardon the Expression) inconsiderable Altitude, and by Planes nothing but Prisms or Cylinders of an Altitude not to be computed: Or at least, by a Sum of Lines and Planes, they denote no finite and determinate, but an infinite or indefinite Sum equal in Number to the Points of some Right Line. From which sort of infinite Sum of inferior *Homogeneals* if any one assert a superior *Homogeneous* to be composed (*viz.* from an Infinity of Right Lines a plane Superfice, of concentric Peripheries a plane Circle, of plane or curve Superficies a solid Body,) which the great *Gallilæus* doubted not to assert, he will easily be convinced of Error, or contradicted. But however, passing by this Controversy, that Use can be no Offence to our Doctrine; for this Precept is of irrefragable Force in the Opinion even of those who embrace that Method with both Arms, *viz.* *That Things heterogeneous cannot be compared together by a definite Quantity or Number.*

Which Thing though it be so apparently true and in the highest Sense agreeable to Reason, yet our Countryman Mr. *Hobbs* (as I have already shewn in Part) has lately controverted it, and as much as he was able covered a Thing so clear in a thick Mist. He feared not to compare *Lines* and *Times* together, as *homogeneous Quantities* obtaining a *mutual Proportion*, though Things of the most distant Nature. For because Longitudes run through by Motions of equal Celerity are to one another as the *Times*: By *Permutation*, says (*f*) he, *it will be,*

(*f*) De Corp. cap. 16.

as a Time is to a Longitude, so is a Time to a Longitude. As if he should say, Because a Furlong is to a Thousand Paces, as one Hour to eight Hours; Therefore permutably, as a Furlong is to an Hour, so is a Thousand Paces to eight Hours; than which kind of Argumentation nothing can be more absurdly ridiculous, as any one may easily perceive. The same Person says in the Dialogues wherein he professes to examine and amend the modern Mathematics (but I wish he had more diligently examined and amended his own; (g) *As the Quantity of a Weight will be to the Length of the Line which represents it, so will the Quantity of twice the Weight be to the Length of twice the Line representing it.* And being reminded of this Error by his Opponent, instead of laying it aside, he coined new Definitions and Acceptations of Words in his own Excuse or Defence, as well less consonant one with another, as more remote from common Use, and for the most Part repugnant to his own Conclusions, and devised strange Pretences contrary to all pure Reason, which it will not be foreign to the purpose to shew, in a few Words, both for the sake of illustrating the Matter in Hand, and to prevent others from falling unwarily into the like Faults, by shewing how circumspectly all ought to behave in these Things. He defines *Measure* this Way; (b) *Measure is one Magnitude of another, when it, or its Multiple, being applied to another coincides with it.* And again in Words a little different, but in the same Sense; (i) *Measure is a Magnitude of a Magnitude, a lesser of a greater, or not a lesser, when the lesser being once or oftner applied to it is equal to it.* According to which Definitions it appears, that *Measure* is nothing else but some Part of a Thing measured, which being some Number of

(g) Dial 3. p. 80. (b) Dial 1. p. 11. (i) Dial. 2. p. 43.
Times

Times taken, so exhausts the Whole, as to leave no Remainder, as the Words (*k*) μέτρον, μετρεῖν, καλαμετρῆν are mostly or always accepted in the *Elements*, as has been shewn. Moreover he defines (*l*) *Homogeneous Quantities to be those, one of whose Measures may be applied to the other, so that they may be congruous: And whose Measures are accommodated to one another.* But Measures, as was just now seen, are with him, the Aliquot Parts of Quantities. Therefore to make him consistent with himself, those Quantities will be *homogeneous* whose *aliquot Parts* are capable of Congruence. But the *aliquot Parts* of a Quantity of Time are no other than Quantities of Time, nor of Weight than Quantities of Weight, nor of a Line than Quantities of a Line, nor of a Body than of a Body. Therefore since none can conceive how a Quantity of a Line can be applied to a Quantity of Time (*viz.* the Quantity of a Line of one Cubit to the Quantity of a Year of Time, or an Ounce of Weight) so as to agree or coincide with it; therefore Lines will not be *homogeneous Quantities* of Time and Weight, according to his own Definitions and Hypotheses. Thus would common Logic infer, but with a strange Sagacity he concludes the contrary; *Because* (says (*m*) he) *a Quantity of Time may be measured by a Line, and a Line may be applied to a Line, therefore a Quantity of Time will be homogeneous to a Quantity of a Line.* Behold the Source from whence most of the Absurdities flow with which these Dialogues abound. *Because a Quantity of Time, says he, may be measured by a Line:* But pray, ingenious Sir, be pleased to look back at your own Definition, and see whether according to it, a Line can be a *Measure* of Time, or (because you rather love to speak more intricately) a Quantity of Time, *i. e.* whether a

(*k*) Pag. 110. (*l*) Dial. 3. p. 80. (*m*) Dial. 5. p. 110.
X
Line

Line can be any *Aliquot Part* of a Quantity of Time, or a Quantity of Time be made up of Lines, or a Line be a Quantity of Time (for an aliquot Part of a Quantity of Time is an aliquot Part of Time;) and by a like Reason whether a Line be an aliquot Part of a Superfice, of a Body, a Weight, or any other Quantity; or whether all Quantities may not be altogether composed of Lines, *viz.* whether or no the Quantity of a Year or a Month, an Ounce or a Pound, a Square or a Cubic Foot, are Lines, or constituted of Lines: Or if you advance any of these Things will you not justly make yourself ridiculous to him that hears you? But this learned Man has not considered enough how much he departs from his own Definition in the Use of the Word *Measure*, and thereby ministers the Occasion of his own falling; and when he calls a Line so often taken a *Measure* of Time, Weight, or of any other Quantity, he cannot mean that a Line is an *Aliquot Part* of a Time, a Weight, a Motion, or a Body, or that a Line can be congruous with these; but *Measure* is used in the more loose Signification, according to which, as we have more distinctly explained heretofore, *Measure* does often design *any Thing, which may either conveniently represent or any Way notifie another.* In which twofold respect a Line (especially a right or circular Line, because of their Simplicity and Uniformity) is wont to be called the *Measure* of Time, Weight, Velocity, or of any Quantity whatsoever. For because every *Reason* of Quantities may be expressed by *Right Lines*, therefore *Right Lines* are most commodiously applied for representing them; as *ex. gr.* for two Solids, one of which is in Proportion to the other, as $\sqrt{2}$ to 1, or as the Diameter of a Square to its side, (when nothing is to be considered but their *Proportion*;) may be substituted two *Right Lines* exhibiting their Reason: And by like

Reason may two *Right Lines* be assumed for exhibiting the *Reasons* of two Times or two Weights ; and so far may those Lines in the widest Acceptation be called the *Measures* of these Quantities : In which Sense Numbers are the *most common and usual Measures* of *commensurable Quantities*, expressing their *Reasons*, and being substituted for them in a Course of arguing. And not only Lines, but even any Quantity whatsoever may be a *Measure* in Respect of any other : for as every Quantity may be represented by a Right Line taken at Pleasure, so may it be equally designed by any Superfice, Body, Letter, Character, or Name. A *Right Line* then obtains, (and by like Reason every other Magnitude may obtain) the Name of a *Measure* still more properly, though at the greatest Distance from Mr. *Hobbs's* Definition, as it may serve for determining or declaring the Quantity of other Quantums ; as the Longitude of the Line, which any moveable Thing runs through in any assigned Time, declares and discovers its Velocity and consequently its Measure ; and a circular Arch intercepted between the Legs of a rectilinear Angle shews *i. e. measures* (according to this Acceptation of the Word *to measure*, which we have largely explained already) the Quantity of the Angle. If therefore he with whom we are contending had thoroughly perceived or weighed this Ambiguity of the Word *Measure* ; or if he had stuck more constantly to his own Definition : I imagine he would not thus have confounded the Quantities of all Things and pronounced them *homogeneous* to one another in the Strength of such an Argument. Because a *Line*, he argues is a *Measure* of *Time*, the *Quantity* of *Time* will be *homogeneous* to the *Quantity* of a *Line*. But I answer a *Line* may be called the *Measure* of *Time* by taking a *Measure* for a Symbol, Argument, or Index of the Quantity

which *Time* has ; but taking *Measure* according to his Definition for an *Aliquot Part*, it sufficiently appears, nor does he deny, that a *Line* is not the *Measure* of *Time*, and consequently even according to his own Definition of an *Homogeneous*, the *Quantity* of a *Line* will not be *homogeneous* to a *Quantity* of *Time*. Nay by the same Argument with which he goes about to prove that the *Quantities* of *Time* and a *Line* are *homogeneous*, it is equally concluded that the same are *heterogeneous*, viz. because a *Quantity* of *Time* may be *measured* (i. e. designed, declared, or notified) by a *Parallelogram* or a *Cylinder* ; and a *Line* cannot be congruous to a *Parallelogram* or *Cylinder*, according to his Definition of *Heterogeneity*, therefore they are *heterogeneous* to the *Quantity* of a *Line*. Nay farther all *Quantities* whatsoever are both *homogeneous* and *heterogeneous* at the same *Time* : for *They* (says (n) he) *are homogeneous which are measurable by the same Kind of Measure* ; therefore since all *Quantities* are mensurable by *Lines*, they will all be *Homogeneous*. And these *Quantities* are *Heterogeneous* (as the same *Person* teaches) *which are measured by a different Kind of Measure* : therefore all *Quantities* are *Heterogeneous*, because they all may be measured by *Lines*, *Superficies*, or *Solid Angles* (most by rational or surd *Numbers*) viz. in the *Way* he takes *Measure*, when he is framing his false Arguments. And indeed all his Arguments relating to this Subject seem to labour under this one Fallacy of *Ambiguity* : for really those Things are *homogeneous* that are determined by the same *Kind of Measure*, taking *Measure* for a *Part* or something congruous to the Thing measured ; but they are not always *homogeneous* which are measured by the same *Kind of Measure*, taking *Measure* for a *Sign* or *Argu-*

ment of the Thing measured ; thus indeed there would be no *Heterogeneity* of Quantities, and the Controversy would be easily put an End to.

But he expects to extricate himself out of these Difficulties by distinguishing very subtilly the *Quantities* of Things from the *Quantums* themselves. *The Quantity* (says (o) he) *of every Thing in the abstract is homogeneous to the Quantity of every other Thing, and therefore the Quantities of Lines, Surfaces, Solids, Time, Motion, Force, Weight, Strength, Resistance are homogeneous, though the Things themselves are heterogeneous.* Again, *I see now, though it be absurd to say a Line is equal to a Time, yet it is not absurd to say the Quantity of a Line is equal to a Quantity of Time.* And in other Places here and there he inculcates this wonderful Comment. Whereby notwithstanding he effects nothing ; but only spends Words upon us, or rather upon himself. For I am pretty sure that he can conceive nothing by that *abstract Quantity* he speaks of, which is different from a Line or a Time themselves. What, pray, is the Quantity of a *Line*, but the particular and determinate Magnitude of that *Line*, or the *Line* itself whereby it is so determined ? What the Quantity of a *Time* but a definite Extension of that Kind, or the *Time* itself, as so extended ? Therefore if a *Line* and a *Time* are *heterogeneous*, their *Quantities* will be also *heterogeneous*. And that a *Line* and a *Time* are Things *heterogeneous*, not only as Physical Things, but as subject to Mathematical Considerations, himself, being constrained by the too great Evidence of the Thing, does scarce deny. But how are they *heterogeneous* ? not as *Hot* or *Cold*, *Black* or *White*, but as *Great* or *Little*, *i. e.* as *Quantities* ; for a Mathematician considers them no

otherwise; Why? because they have no mutual Habitude or Relation, nor can be compared together, according to Quantity, as *Euclid* truly teaches, i. e. because they are not Quantities after the same way, but have each a Quantity of a different Kind; or because it cannot be said without great Absurdity, that so much of *Time* is equal to so much of a *Line*, or that a Year is as much as a Furlong. Therefore the Quantities of a *Time* and a *Line* are of a different Kind.

But he replies, *The Quantity of Time is measured by a Line.* Yes say I again, taking the Verb *to measure* equivocally; i. e. it *measures* not as a *Quantity*, but only as a *Causal*, or *Consequential Sign*; from which nothing can be concluded for his Purpose. I add, that the *Quantity of Time* is not very properly measured, but rather the *Time* itself is measured as a *Quantity*, or as to its *Quantity*; Thus *Whiteness* is not so much seen as the *Body as White* or by reason of *Whiteness*; i. e. because it is so disposed as to affect the Thing seen, after such a manner. From whence neither according to his Definition, that *Homogeneous Things* are such whose *Measures* are *congruous*, are *Quantities* abstractly taken well capable of *Homogeneity*, because they are not measured themselves, but rather the concrete *Quantities* by reason of, or in respect of them; and indeed by reason of them, things are even *Mathematically homogeneous or heterogeneous*.

Yet still it is urged that the *Reasons of Times* are rightly compared with the *Reasons of Lines*: for it is said, that as one Year is to two Years, so is a *Line* of one Foot to a *Line* of two Feet, why then may not the *Quantity of a Time* be compared with the *Quantity of a Line*? But how great is the *Blindness* of such Arguments, to confound the absolute *Quantities* of simple Things with the similar *Reasons* of a *Plurality of Reasons*? Because an
Egg

Egg is to two Eggs, as an Angel to two Angels; or because the Relation of one Egg to two Eggs is the same with that of one Angel to two Angels, can it be any way inferred that the Quantities of an Egg and an Angel are similar and homogeneous? or that the same Measure agrees with the Quantities of an Egg and an Angel? or that an Angel can possess any absolute Quantity at all? But there is no Disparity at all between this and the preceding Instance. An Egg, as it is said, is not liker an Egg. Thus it often happens that they who are more desirous to extenuate or defend their Errors, than ingenuously confess them, don't only decline them, but very often fall into much worse than the former. That proverbial Verse falls in very fitly here.

Μὴ κινεῖν καμαρίαν, ἀκίνητ' ἢ ἀμείων.
Move not that ill, 'tis better let remain.

It follows then because the Quantity of a *Time* (*viz.* of a Year, a Month, or a Day) cannot appositely be compared with the Longitude of a *Line* (*viz.* a Foot, a Cubit, a Furlong) according to Equality or Inequality, Excess or Defect, Addition or Subduction, that they are perfectly *heterogeneous*. And the same Way are all other Quantities affected, in which respect we are not to depart from the common Opinion and Speech of Mathematicians.

But if these Words do sometimes occur in another Sense; as if, because of some subaltern Diversity of Nature any shall call Curve Lines *heterogeneous* to Right, or gibbous to plane Superficies; as *Ramus* calls right rectilinear Angles *heterogeneous* to oblique rectilinear ones (and for almost the same Cause might the Quadrant of a Circle's Periphery be so called to a Sextant, a Line of one Foot to a Line of half a Foot;) or if, because of some peculiar Agreement, Quantities different in Kind

are called *homogeneous*; as a certain Modern (*p*) Geometrician, not otherwise unlearned, does often call a Parallelogram and Cylinder *homogeneous Figures*, because Right Lines parallel to the Basis proceed with a like Tenour in this, as parallel Circles in that; which in his Stile is to proceed by *proportional Principles*. Such out of the Way Novelties of Words, I say, which induce Dark-ness and Confusion upon these clearest of all Sciences, it is better to beware of and avoid; and it would be much safer to refrain from all new Words in expressing our Sentiments, than to forbear using the ancient established ones. But I cease speaking any farther.

I thought to have subjoined some Things to these concerning the *Homogeneity* and *Heterogeneity* of Quantities, about their *Similitude* and *Dissimilitude*: But since the Keeness of my Pen has already overshot the appointed Bounds of Time, let so much suffice for paving the Way to those Difficulties concerning the *Analogy* of Quantities, which are next to follow, when a fit Occasion offers. In the mean Time I bid you Farewell.

congra-

congratulating your present Health, and wishing it a long Continuance to you hereafter) I apply myself to the Business, and resume my too long intermitted Task. But, with your leave, permit me to stick close to my former Method, and finish out what remains of my Undertaking, concerning the Preparatives to the Mathematics, which I hope to effect with this Term; that after we have stuck so long upon the Shore, and cruised along the Coasts of these Sciences, we may at length be carried out into the Main Sea. Though in Truth the Subjects we are now undertaking to discuss, whether we respect their Subtilty or Utility, do seem not to be far from the very inmost and deepest Part of the Mathematics. For *Reason* or *Proportion* is first to be considered, then *Analogy* or *Proportionality*; about which the Whole of Mathematics is some Way or other employed either as its Objects or Instruments of Invention and Demonstration; and therefore the divine (a) *Plato* in his most divine Work (I mean his (b) *Timæus*) thinks it to be the *Chain and Bond of the Mathematics*, or rather of *all Disciplines*. Nor does the most illustrious Author of the famous Discourse concerning the Method of using Reason, differ from hence. *Because*, says (c) he, *I observed that those (viz. particular Sciences called the Mathematics) although conversant about different Objects, did yet all agree in this, in examining nothing but certain Relations and Proportions, which are found in them, I thought that these Proportions only are to be considered.* I add *Eratosthenes*, who pronounces, *That all Things in the Mathematics consist of the Proportion of certain Quantities.* Therefore the Consideration of *Proportions* pervades and

(a) Theon. Smyrn. p. 131.
(c) Pag. 18.

(b) Plato Tim. p. 1048.

in a manner contains the Whole of these Disciplines: So that while we are contemplating the Nature of *Proportions* we ought not to think we are touching the outward Skin, but are entering their very Pith and Marrow. The Theory of the determinate Situation or Position of Magnitudes will succeed this, whereby the various Similitude and manifold Diversity of Figures appears, together with their *Proportion*; next, of the *Species* or *Specificall Agreements* and *Differences* of the Magnitudes consequent to these; lastly, of the Motion whereby Magnitudes are generated: I say, it will remain to consider these. Thus after we have examined the most, at least the principal of all the Properties of Magnitudes, which are laid down by Mathematicians or implied in their Hypotheses, returning into the same Track from which we first departed, we will produce certain Particulars worthy to be observed concerning the Hypotheses themselves and other Principals. Which Business being dispatched, we will apply ourselves to that which, I remember well, was heretofore promised, *viz.* to explain in the Method of Mathematical Invention. And I should be very glad if we could be able to finish this proposed Undertaking within the Course of the present Term. These Things being first spoken of let us first begin to discourse of Reason or Proportion.

As to what pertains to *Reason* and *Proportion* (for these Names are equipollent among most Writers) the *Greeks* design it by the Word $\lambda\acute{o}\gamma\omicron\varsigma$ *Logos* Speech; than which scarce any Word in that Tongue occurs more ambiguous, and of more different Acceptations. *Theon. Smyrnæus* (d) thought it not amiss to recount most of its Significations in an Exposition of those, which are necessary for the

(d) Cap. 18.

reading of *Plato*. But I should seem too much a *Philologer* and ἔξω λόγῳ, i. e. *besides the Purpose*, should I in Imitation of him endeavour to reckon up the most of those, and confirm them by Examples.

It is a known Thing that the Word *Logos* (as the modern *Peripatetics* distinguish it) does commonly denote both the *Internal Speech of the Mind*, and the *External and Enunciative Speech of the Tongue*, both the Faculty operating, and the Operations themselves with the immediate Effects flowing from thence; and especially whatsoever of these is joined with *Discursus* or *Ratiocination*, which is proper to the Nature of Man; he being reckoned the only *Logical*, i. e. *speaking or discursive Animal* among living Creatures. Nor can any one who is moderately learned in the *Greek Tongue* be ignorant that every where among *Greek Authors*, not only particular Sentences conceived by the Mind or delivered by the Mouth are after a peculiar Manner called λόγοι *Logoi*, but also different Mixtures and Systems of many Sentences; viz. *Fables* or *Apologies*, i. e. Words feigned at pleasure; *Trifles* and *Querks*, i. e. mere Talk void of Sense and Reason; *Adagies* or *Proverbs*, i. e. Sentences of common Use; *Rumours* of Fame, or popular Reports, *Stories* of all Kinds, *Orations*, and finally all Letters. Examples might be readily produced to confirm these common Significations of this Word, but I willingly pass them by. Yet I know not but it may be of Use to glance at certain other Acceptations which do also obtain among the Vulgar, as coming nearer to our Purpose and the Sense of Geometry. Such as when λόγος designs any Kind of *Reckoning* or *Comparison of Things together*, as in these usual Phrases, ἀποδιδόναι λόγον to render an Account, συναίρειν λόγον to reckon or compare Accounts, ὑπέχειν λόγον to undergo Examination

tion or be called to Account. Examples of which are in the Holy Scriptures, as that in St. Luke, (d), *Render (or give an) Account of thy Stewardship*; and in St. Matthew (e), *The Lord of those Servants cometh and reckoneth (or compareth Accounts) with them*: Where Account signifies the Account of the Administration of an Office, or of any Thing committed to Trust; which is nothing else but to compare Actions with the Rules prescribed by a superior Power according to which they are directed, or to compare Sums exhibited with those which they lawfully ought or are expected to be. Also when λόγος intimates the *Value, Price, or Worth* of Things, as that is wont to be said, ἐν ἔδει λόγῳ τίθεσθαι *to be placed in no Account*, which is neglected, less esteemed, and debased; and to be ἔδ' ἐν λόγῳ ἔδ' ἐν ἀριθμῷ *neither in Account nor in Number*, which is accounted as Nothing, no where taken Notice of, nor esteemed. Thus *Sophocles*,

Οὐκ ἂν περιμίμῃ ἔδειος λόγῳ βρότον,
 Ὅσις κενᾶσιν ἐλπίσιν θερμαίνεται.

*That venal Mortal is of no Account
 Whose Breast is fired with every flatt'ring Hope.*

Also Ἐν λόγῳ θεῶς ποιῆσθαι *to make Account of the Gods*, i. e. *to worship the Gods*. Λόγον δικαίᾳ ποιῆσθαι *to make Account of Justice*, is an Expression of *Demosthenes*. I add *Galen* (f), *That Name* (says he) *ought to be taken into Account* (εἰς λόγον) *in every Disquisition*. In these Expressions λόγος signifies some Magnitude, Force, or Power of the Things to be estimated. And it seems not much diffe-

(d) Luke xvi. 2.
 (f) De Meth. Med. I. 5.

(e) Matth. xxv. 19.

rent when it is put for the Cause or Condition of a Thing, *i. e.* for that which ought to be considered and is required that something may be done. Thus *Plato* in his *seventh* Epistle to *Dion*, *I promise*, says he, *to come hither on these Accounts or Conditions* ἄπὸ τῶν τοῦ λόγου. Δέχεσθαι λόγον *to agree to the Condition* is used by *Demosthenes*. So, *to be rewarded on the Account* (or *for the sake*) of *Virtue* εἰς λόγον ἀρετῆς, and *to be punished on the Account* (or *for the Sake*) of *Vice* εἰς λόγον κακίας, are Terms of Speech in Use among the *Greek* Orators: *On the Account of Virtue or Vice, i. e.* from the Considerations of *Virtue* or *Vice* examined by *the Rules of Morality*.

I have produced these Instances to make it appear, that the Sense of this Word as applied by Geometricians does not so far recede from its most received Use among other Writers, and the common Way of Speaking. The same might be shewn concerning the Word *Reason* which is here in the Sciences brought to express the *Greek* Word λόγος, and borrows most of its Significations from thence. But because of the exceeding Clearness of the Thing, and the too much Pains already bestowed upon Appendices of this Kind, I forbear. I will only add that the Word λόγος seems to have taken both these foreign Senses and the Sense peculiar to Geometricians, from hence, because in comparing different Things together, their determinate Value or Quantity is declared and expressed from a Respect which one Thing obtains to another. But *Reason* in Latin *Ratio* is derived from the Latin Word *Ratus* judging (or from *Reor* to judge, suppose, or think) and consequently signifies a *Judgment*, *Account*, or *Estimation* of Things known from a Comparison of them. As also the Latin Verb *putare* (in *Greek* λογίζεσθαι) with its Compounds *computare* and *supputare* do signify to *estimate* the

Quantities

Quantities of Things (chiefly as to *Magnitude* or *Price*) by *numbering* or *comparing* them. But the Word *Proportion* is several Times used in *Cicero*, though in a Sense not exactly the same. For sometimes it appears to him to be of the same Importance with *simple Reason*, at other Times to design a *Similitude* or *Analogy* of *Reasons*; and he seems to be the first who invented its Use, at least the first who applied it to the Mathematics: Thus he intimates in the Fragment which is inscribed *Timæus* or *De Universo*. The Words may be thus rendered in *English*. *But that is the fittest and fairest of Ties which, from itself and with Respect to these Things that it binds, most especially effects one. And that, which by the Greeks is called Analogy, most completely reaches it, which in Latin, (for we must presume, because these Things are first innovated by us) may be called Comparison or Proportion. Moreover in that Book the Word Proportion is often used, yet in a Sense something various.* The Origin or Occasion of inventing which Term seems to be taken from hence. When in gathering Tributes and publick Taxes, every one had his Share to pay, according to the just Value of his Estate, which Share was called each Man's *rated* or *computed Portion*; hence every one was said to pay *pro Portione*, or *pro rata Portione*, *i. e.* according to his computed Portion: And hence proceeded the Word *Proportion*. This is the Opinion of *Cicero*, while he was studying to suit the *Greek* with his *Latin*, that he might express the Words *λόγον* and *ἀναλογίαν*, which are obvious to any one who looks into *Plato* and the other *Greek Philosophers*.

But let us remove our Hands from under the Ferula, and going out of the Schools of the *Grammarians* let us see what the *Geometricians* understand by *λόγον*, and the *Reason* and *Proportion* answering

swering to it (according to the more frequent and approved Use of *Proportion*, for sometimes it signifies *Analogy* or *Proportionality*;) And let us enquire what is the genuine Notion of this so common a Word. For it seems strange that there should be so great a Dispute, among Men by no Means of the lowest Rank of Mathematicians, concerning the Nature of that which every where occurs in the Mathematics, and well nigh makes the Whole of that Science. As if a Thing so plain, so usual, and so diligently examined were not to be known. From whence can this proceed? I suppose from thence; that it is very difficult either distinctly to imagine, or accurately define Things very abstract and universal, and especially the Modes and Relations of Things. I believe that there are scarce any, at least among such as are skilled in the Mathematics, who do not sufficiently understand what they mean themselves when they pronounce this Word, and what others conceive pronouncing it; but they are not perhaps so ready to explain in other Words or define their own or other Peoples Conceptions answering to it. Hence arises a Cause of Dispute in this, as in most other such like Matters which are disjunct from the Sense: *Cartesius* has noted this, and thence esteems that morose Curiosity of defining Words as a Fault in Philosophers, in these Words; *(f) I do not explain many of those Names, which I already have used or shall use in what follows, because they seem to be sufficiently known of themselves. And I have often observed Philosophers to err in this that they attempted to explain those Things, which were most simple and known of themselves by Logical Definitions; for thus they rendered them more obscure.* Which Observation of this

(f) Princ. I. 10.

most subtle Person is most strongly confirmed from hence ; because there is seldom any Agreement about these Definitions, at least among those who have given up their Name to no Sect ; but what one approves the other disapproves, or judges less fit, or not sufficiently accurate : As also from hence ; because the Definitions of those most abstract Names do rarely or never enter Demonstrations, nor serve for drawing Conclusions, which yet is the principal Use and Design of Definitions. For Instance, I observe by the Way, but very opportunely, that the Definition of the Word λόγος is no where to be found in the whole System of the Elements, nor is elsewhere cited (that I know of) in any Mathematical Book, for erecting any Demonstration, or deducing any Conclusion. The Word *Diastema* among the ancient Musicians may afford another Example, which they all defined, but all differed in Words, and varied something from one another in the Sense: This will appear to any one that pleases to consult *Aristoxenus*, *Euclid*, *Nichomachus*, *Bacchius*, *Aristides*, *Gaudentius*, *Capella*, &c. But to come nigher the Purpose.

First it is to be noted, that there is a certain Ambiguity or Distinction of the Words *Reason* and *Proportion*, even as they are used by Mathematicians, though not, I imagine, of the Greek Word λόγος. *Reason* or *Proportion* according to some is twofold, viz. *Arithmetical* and *Geometrical*. For the better understanding of which, it is first to be premised that each Kind of *Reason*, as it intimates any Comparison of *Homogeneous Quantities* belongs to that Class or Category of Beings which *Aristotle* calls τὰ πρὸς τι ; and others *Relations* or *Habitudes*. The two Correlatives of which Relation are by Mathematicians called *Terms*. *A Term* (says *Theon Smyrnæus*) is that which expresses the particular

particular Nature or Property of the Things mentioned, as Number, Magnitude, Power, Bulk, Gravity. Or elsewhere more clearly: (g) *We call those Terms which, agreeing in Genus or Species, are assumed in Comparison.* And the former of these two Terms in the Comparison is called the *Antecedent*, the latter the *Consequent*. This being premised, some, with the ancient Scholiast cited by Meibomius, call *Arithmetical Reason* or *Proportion the Relation of two Quantities as to Difference*, i. e. *as one exceeds or is short of the other*: and it may be added, *as to Equality too*, i. e. *as they differ nothing from one another*; for there may be also a Comparison made between *equal Quantities*, and this particular Relation of the same may be signified by having for their Difference *nothing*, which is the Middle Limit between Excess and Defect. By *Difference* I here do not understand any absolute Quantity remaining after the Subduction of one Term from another (such as indeed is generally called $\Delta\iota\alpha\phi\epsilon\rho\epsilon\iota$ *Difference*) but the *Comparison* or *Reference* in a singular Manner of this to that. *Ex. gr.* The Relation between a Line of three Feet and a Line of two Feet, according to which that is conceived to exceed this by a Line of one Foot; or inversely, the Relation of two Feet to three Feet, as that is conceived to fall short of this the Quantity of a Line of one Foot; these are called *Arithmetical Reasons*, the former of *Excess*, the latter of *Defect*; yet the absolute Magnitude of the Line of one Foot, though it usually goes by the Name of *Difference*, is not the *Arithmetical Reason*; but this exceeding or falling short is called the *Arithmetical Reason*. Such a *Habitudo* (I say) of Quantities to one another do some call *Arithmetical Reason*. I will not now dispute

why they stile it *Arithmetical*, because the Thing is controverted; I only say that it seems to be thus denominated because the Ancients termed a certain *Analogy Arithmetical*, of which it will be proper to speak when we come to treat of *Analogies*.

But among the *Greeks* I no where find any *Arithmetical λόγος*; on the contrary they always distinguish the λόγος of *Quantities* from their *Difference* which they denote by the Words διαφορά and ὑπεροχή; and sometimes term διάστημα, *i. e.* an *Interval, Space, or Distance*, not thereby intimating any *Interstice* resulting from *Local Position*, but a *Diversity*, and as it were *Distance* in *Quantity* by which one cannot be equal to another, or a certain *determinate Removal* from *Equality*; but by λόγος they continually designed that *Habitude* of *Quantities* which is wont to be called *Geometrical Reason*, or simply *Reason*. For when *Reason* is put at large, always *Geometrical Reason* is meant, *i. e.* that ἄριστος *Habitude* according to which one *Quantity* is conceived some *Number* of *Times* to contain or be contained in another. *Ex. gr.* the *Relation* of a *Line* of three *Feet* to a *Line* of two *Feet* (according to which the former is conceived to include the latter *once* and *half as much* besides, or is to the latter as *three* to *two*), is called a *Geometrical Reason*, or particularly a *Sesquialter Reason*: and inversely the *Relation* of a *Line* of two *Feet* to a *Line* of three *Feet* (according to which the former makes *two third Parts* of the latter, or is to the latter as *two* to *three*) is called a *Subsesquialter Reason*. Whence it may appear how much *Difference* there is between these two *Relations* called *Arithmetical* and *Geometrical*. For it is very different for one *Quantity* to exceed another, and for one *Quantity* so often to contain another, or for one *Quantity* to fall short of another,

other, and for one Quantity to be contained in another. This Diversity is commonly not ill explained from the *Manner* whereby these *Relations* are investigated and known, especially then, when the *Terms compared* are expressed in Numbers (I am against this Exception, because by reason of that Neglect the Doctrine of *Reasons* is either unadvisedly or obscurely delivered :) But let us suppose the *Terms compared* to be expressed in Numbers; then their *Arithmetical Reason* is found by subducting the *Consequent Term* from the *Antecedent*, and the *Geometrical* by dividing the *Antecedent Term* by the *Consequent*; I say found, *i. e.* discovered and subjected to our Estimation. *Ex. gr.* by comparing two Quantities denominated by the Numbers *Three* and *Two*, suppose *three Feet* and *two Feet*, by subducting *Two* from *Three* there is left *One* for the Difference, or a Line of *one Foot*. But, the Terms being transposed, if the Line of *three Feet* be taken from the Line of *two Feet*, there remains *less one*, or the *Defect* of a Line of *one Foot* for the *Difference*; and from these Remainders are known the *Relations as to Difference*, or the *Arithmetical Reasons* of the proposed Quantities; since if the Residue found by both Subductions be added to the *Consequent*, the Sum resulting will be the *Antecedent*: For in the former Comparison $1 + 2 = 3$, and in the latter $-1 + 3 = 2$. And this seems to be the Tendance of every Comparison of Quantities, that other Comparisons may be reduced to, and some Way estimated by *Equality*, which is the most simple, constant and comprehensible *Relation*. The former *Relation* from the former *Difference* is called the *Relation of the Excess of one*, the latter from the latter *Difference* the *Relation of the Defect of one*. But if two Quantities represented by the Numbers 20 and 4 be compared, by dividing the *Antecedent* 20 by the

Consequent 4, the *Quotient* is 5 ; but inverting the Terms, by dividing 4 by 20 the *Quotient* is $\frac{4}{20} = \frac{1}{5}$. By which *Quotients* are declared the *Geometrical Reasons* of the proposed Quantities, because if the *Quotient* found be multiplied by the *Consequent*, the *Product* is equal to the *Antecedent* : for in the former Comparison $5 \times 4 = 20$, in the latter $\frac{1}{5} \times 20 = 4$; as Things again are referred to *Equality*. The former *Relation* by the *Quotient* found is denominated a *Quintuple Reason*, the latter *Subquintuple*. But I must now shew a Cause why I have explained *Arithmetical Reason* otherwise than it is vulgarly done, not by *subducing* the lesser Term from the greater, but indifferently the *Consequent* from the *Antecedent*. For which many Causes may be assigned ; as

First because this Way is more commodious for shewing the Diversity we are insisting upon, of these different *Reasons* by *Subduction* and *Division* ; because this Way the *Subduction* which signifies an *Arithmetical Reason* in every respect answers the *Division* which signifies a *Geometrical*. For according to us the twofold *Subduction* in the former is the same Way performed as the twofold *Division* in the latter : There the greater Term is improperly *subducted* from the lesser, as here the lesser Term is improperly *divided* by the greater : As the *Remainder* there is less than *Nothing*, so the *Quotient* here is less than *Unity* ; and as the *Antecedent* there is always made by the *Addition* of the *Consequent* and *Remainder* ; so the *Antecedent* here is formed by the *Multiplication* of the *Consequent* and *Quotient* : Therefore this Method is more commodious than the other, according to which the *Subduction* or *Difference* is of one Sort only, *viz.* *Positive* or greater than *Nothing*, and the other Properties do no how agree.

Secondly,

Secondly, this Way of explaining *Arithmetical Reasons* by *Subduction* is also more true in itself, and more agreeable to the *Reason*. For since a Transposition of the *Terms* in comparing two unequal Quantities causes a twofold *Relation* (for the *greater Term* is not the same Way referred to the *lesser*, as the *lesser* to the *greater*) by the Acquisition or Invention of *one only Difference*, from the *Subduction* of the *lesser* from the *greater*, therefore these two *Reasons* are not rightly and usefully explained; but it is better to express them by *two Differences*, the one *Positive* shewing an *Excess*, the other *Negative* signifying a *Defect*. *To lack* and *to exceed* are not the same, and therefore ought not to be denoted by the same Sign. This being unobserved by some, they asserted that there is no *Relation of Quantities as to Difference*; because if there be, it ought to be twofold; but a *Positive Difference* is simple and One. *Nichomachus* in his *Enchiridion of Harmonies* says: *They who account a Difference and Relation for the same, think Wrong; for to two has the same Difference to one, as one to two, but not the same Relation.* Consequently he argues aright from the Hypothesis of one only *Difference*; but I answer that the *Difference* between 1 and 2 is -1 , as signifying 1 to lack one of 2; but the *Difference* between 2 and 1 is $+1$, as signifying 2 to exceed 1 by one. Therefore since the *Difference* is twofold, nothing hinders, but there may be two *Relations*, as it were contrary to one another or universal. Therefore *Theon Smyrnæus* thinks wrong with *Nichomachus*, *That the Difference of two unequals, either to other, is one and the same, but the λόγος, i. e. Geometrical Reason of either to other is different and contrary.* Indeed I can hardly perceive why *Geometrical Reasons* which lie between two unequal *Terms* ought not to be equally confounded from a Transposition of the

Terms and accounted for one *Reason*, as the *Relations according to Difference* which lie the same Way between unequal Terms are vulgarly esteemed for one. Nor does any Thing hinder but there may be such an improper *Subduction of a greater from a lesser*, and what perhaps seems difficult to conceive, *Something less than Nothing* itself. For the *Division of a lesser by a greater* is scarce thought less improper, nor is it easier to conceive how often a *greater is contained in a lesser*. It is enough that this Kind of *Subduction* is subject to Arithmetical Laws as well as that Kind of *Division*, and is not devised or applied without Cause.

It may be added that this Method of *Subduction* is very useful in other Respects, especially in the Comparison of *Geometrical Progressions* with *Arithmetical*; and chiefly of those *Progressions* which proceed on one side by *encreasing* and on the other by *decreasing* from *Unity*: For as *Positive Exponents* are assigned to the *encreasing Terms*, so *Negative* ones are attributed to the *decreasing Terms*. But here is no Place for speaking farther of this. I only take notice, that these *Negative Differences*, or *Terms less than Nothing* are easily exhibited in Geometry. For they are only computed from the same fixed Limit, in an Order contrary to those wherein the *Positive Terms* proceed, or such as are *greater than nothing*. As in a Right Line (FIG. V.) extended indefinitely are assumed the two Right Lines AM, AN, towards the contrary Parts, each being equal to any Right Line Z, and let the Right Line AM proceeding forwards be represented by $+Z$, then will the Right Line AN taken backwards be represented by $-Z$. As suppose one swimming forwards and aiming against the Stream towards M, be carried backwards by a double Force, then the Distance he has made will be $AM - 2AM$ or $-AM$ to be computed from A backwards to N. These

These Things may in part suffice for illustrating the *Diversity* between *Arithmetical* and *Geometrical Reasons*, by *Subduction* and *Division*. We will perhaps hereafter treat of the same Thing more opportunely and accurately, when their Opinion comes to be examined, who would confine the *Doctrine of Reasons* and what belongs to that Disquisition to Numbers. We shall now only touch upon one or two *Diversities* of these *Relations* drawn from their Nature. *First* of all it is to be noted, that the same *Arithmetical Reason* is exhibited in *Terms* of one Kind only, but a *Geometrical Reason* may be fitly represented or expressed by *Quantities* of any Kind. The Reason is, because an *Arithmetical Reason* is determined by something absolute within the Limits of a certain Genus *viz.* by the *Difference* of two *homogeneous Quantities*, which is always *homogeneous* to the *Terms* themselves so compared: But a *Geometrical Reason* is determined from the *Manner* whereby one Thing contains or is contained in another, which *Manner* may be equally agreeable to the *various Conjugations* of *heterogeneous Terms*; whence it comes to pass that every two *Quantities* are capable of expressing or subjecting to Estimation the *Relations* of any other two *Quantities* the same Way affected. *Ex. gr.* The *Arithmetical Reason* of two unequal Lines can be exhibited only by two Lines, not two Weights, Times, or Bodies; because no Line exceeds another by any Weight, Time, or Body, but only by a Line determined according to its own absolute *Quantity*: But the *Geometrical Reason* of the same two Lines may be expressed by two Weights, two Times, or two *Quantities* of any other Kind; as the *Reason* between a *Foot* and an *Inch* in Length may be represented by a *Pound* and an *Ounce Troy* in Weight, by a *Year* and a *Month* in Time, or by any other similar *Terms*, of which

one contains the other *twelve Times* ; because the *Terms* of these *heterogeneous Conjugations* being compared together according to their absolute *Quantities* do respect one another the same *Way*, and are the same *Way* affected towards one another. From hence a most learned (*b*) Man takes Occasion to say that all *Geometrical Reasons* of whatsoever *Quantities* are homogeneous to one another, because all are in the *Genus* of *Number*. And afterwards he adjoins. *Where a Comparison is made in respect of Reason, the Reason which emerges of the Things compared does not seldom leave their Genus and pass into the Genus of Number ; of whatsoever Genus the Things are, which are compared.* Which Words notwithstanding I do not so well approve of, as well for other Causes not yet to be explained, as because I know of no *Genus* either of *Reason* or *Numbers* comprehended under *Quantity* : For neither in my Opinion are *Reasons* *Quantities*, nor capable of *Quantity* (as hereafter I shall endeavour to evince in its proper Place) but are *mere Relations* founded in *Quantity* ; and *Numbers* I account only as the *Names* and *Symbols* of *Quantities*, which we have already shewn more than once. I add, it seems manifest, that when two *Quantities* are compared together (*viz.* to investigate their *Reason* by certain artificial Operations *Arithmetical* or *Geometrical, i. e.* to render it comprehensible or estimable) yet there is not thence framed any new *Reason* but the same exhibited in other *Terms* ; nor does the *Reason* ever leave its *Genus*, but is exhibited in *Terms* of a different *Genus*, for the most part more simple and known ; indeed generally in *Numbers* when it may be done, because these are *Symbols* most accommodate to our Capacity for determining the *Measures* of *Things*, *Ex. gr.* to him that enquires what *Reason* a *Shilling* has to a *Groat* in

(*g*) D. Wallis's Arith. p. 226.

Value,

Value, or in Weight, he that answers, It has the *Reason* of 12 to 4, produces no other *Reason*, but explains what is sought in *Numerical Terms*: and moreover he who asks what is the *Reason* of the Number 12 to 4, and dividing the *Antecedent* 12 by the *Consequent* 4 finds it to be *triple*, mentions no new *Reason*, but expresses the *Reason* proposed in *Terms* more easy to be estimated, *i. e.* in the *least Numbers*, *viz.* 3 and 1. For he who says that is *triple* to this, says and means no more than that is to this as 3 to 1; the *Antecedent* being expressed, and the *Consequent* (which is always Unity in the Denominations of such *Reasons*) understood.

Hence may another *Diversity* of these *Reasons* be taken notice of, that a *Geometrical Reason* is always expressed by *two Terms*, at least in the Understanding, and those always *Positive*. For the *Reason* even of two *Negative Terms* is *Positive*, *ex. gr.* the *Reason* of -4 to -2 is *Double*, or as 2 to 1, because multiplying each Term by -1 there is produced $+4$ and $+2$. But an *Arithmetical Reason* is expressed by only *one Term*, and that sometimes *Negative*: as such a *Reason* between 1 and 3 is most commodiously denoted by the *Negative Term* -2 , as was just now shewn. Moreover an *Arithmetical Reason* is found between two *Terms* affected with different Signs; but there is no *Geometrical Reason* between such. *Ex. gr.* the *Arithmetical Reason* between 2 and -2 is all one as the *Reason* between 6 and 2; for the *Excess* of the *Antecedent* above the *Consequent* in both is 4; but 2 to -2 has no *Geometrical Reason*; for the former is to the latter, as something is to what is less than infinitely little; nor is there any imaginable Number how great soever which is not lesser in Respect of 1, than 2 is in Respect of -2 .

Again the *Geometrical Reason* of *Equals* is always denominated by *Unity*, and the *Arithmetical Reason*

son by *Nothing*; the *Geometrical Reason* of a *greater* to a *lesser*, if explicable in Numbers, is denominated by a Number exceeding Unity, integer or mixed, the *Arithmetical Reason* by a Difference exceeding *Nothing*, which yet is not always as much as Unity; but the *Geometrical Reason* of a *lesser* to a *greater* is always denominated by a Fraction or Number less than Unity, and the *Arithmetical Reason* of such *Terms* is signified by a Number beneath *Nothing*, involving Negation, as we have already inculcated. But we have spoke more than enough concerning the *Differences* of *these Reasons*.

Since therefore these *Relations* are so different by Nature, the same Name of *Reason* will not agree with both univocally; and consequently it is better to appropriate that Word to *Geometrical Reason* alone. Therefore dismissing that which is called *Reason* without Authority, let us come to examine the Notion of this *Geometrical Reason* a little nearer. Let it suffice to have cleared the Way at present which lay blocked up with Ambiguities; and in the next Lecture we will follow it more closely: In the mean Time, I wish you Farewell.

L E C T U R E XVIII.

*A Defence of Euclid's Definition of Reason
or Proportion.*

LAYING aside all Prefaces, and having dispersed the Clouds of Ambiguities, which lay in our Way, we come now to enquire into and explain the Nature of *Geometrical Reason*. *Geometrical Reason* or simply *Reason* (for in this Sense

we

we will always hereafter use this Word, as also its equivalent, *Proportion*) I say *Reason* or *Proportion* ὁ λόγος is defined by *Euclid* (or by *Eudoxus*, if he, as is said, be the Composer of the fifth Book of the *Elements*) to be a *certain Habitude* (or *Relation*) of *two homogeneous Magnitudes to one another, according to Quantity*. About which Definition *two Things* may be enquired into and disputed; *first* what is his genuine Meaning; and then whether it be sufficiently just and accurate. I will endeavour to satisfy each Disquisition applying certain Observations to his Terms, that we may at the same Time interpret the Sense, and defend the Authority, of our Master. Be pleased to pardon my Contentiousness, and take it not for the worse that being led with a certain Piety I study to vindicate the *Father* and *Prince* of Geometry from the undeserved Reproaches, which are every where thrown upon him.

1. In every Definition, Care is to be taken that the Thing defined be restrained to a certain Classis of Beings; for that conduces very much to determine its Nature and distinguish it from others. Therefore the Genus is first to be enquired into, which in this Definition is (i) *Habitude*, or *Relation*, and that rightly; for since every Quantity may be considered two Ways, either as having a certain absolute Extension of its Genus (absolute, I say, and determinate from the intrinsic Property of its Nature;) or as, in Comparison with another Quantity, *it has itself in a certain Manner* towards that other: The Comprehension of which *Manner* is serviceable for the better Conception of its absolute Quantity and the Declaration of others. I said, *it has itself in a certain Manner*, i. e. as either wholly congruous and equal to it, or unequal in some peculiar *Reason*, which is rendered known

(i) Σχίσμα.

and

and computable by Numbers, *i. e.* by Symbols of the Quantities divided into equal Parts, or by the Exposition of other Quantities which are to one another *in the same Manner*. I beg pardon for spending a little more Labour than ordinary in illustrating a Thing so very difficult to be explained, and well nigh too subtle for the most attentive Mind. But when a Quantity *has itself in a certain Manner to another, i. e.* is thus equal to another, or in a certain Reason unequal, it is said (by Agreement of the Masters who prescribe Names to the Things considered in this Science) *to have this or that Reason to that other*; and such very *Respect* abstractly taken is named *Reason*, which consequently is rightly added to the Classis or Category of Relations. For it is apparent that the Quantities thus considered are *mutually referred to one another*, and do undergo all Things which Logicians assign to *Relatives* or *Correlatives*; and *Aristotle* takes his first Examples of his $\tau\acute{\alpha}\ \pi\rho\acute{\sigma}\ \tau\iota$ (*i. e.* Things referred to another) from hence both in his *Logics* and *Metaphysics*: *Those Things* (says he) *are said to be to one another* (*i. e.* to be *Relatives*) *which as to that very Thing which they are, are said to be of others, or are some other Way referred to another: as a Greater, whatsoever it is, is entirely attributed to another, for it is greater than something: and also a Double whatsoever it is, is attributed to another, because it is the double of something.* Nevertheless our Countryman the wonderful Corrector of Modern Mathematics is most unmerciful and unmannerly with *Euclid* upon this Account. *The Definition of Reason* (says (k) he meaning *Euclid's*) *is sufficiently unapt.* Again, *As Euclid had insignificantly said.* Again, *It may be that Euclid himself did not sufficiently perceive the Nature*

(k) Pag. 44. 100. 88. 82.

of Reason ; nay it could not be otherwise, since he defines Reason by ποιά σχέση, i. e. a certain Habitude or Relation. And again he reckons that Euclid has coughed in this Place, i. e. he has given us an empty Sound, because he had nothing to say to the Purpose. But good Words I beg, what Reason is there for all this tragical Outcry ? Is it because Euclid has defined Reason by σχέση, i. e. a Habitude or Relation ? Pray what can you conceive by σχέση, or you would have it to signify Nothing ; what does the Man mean ? Himself like all others defines Reason truly and accurately thus ; (1) Reason is the Relation of the Antecedent to the Consequent according to Magnitude. Reason is a Relation, and what else did Euclid think or mean ? Who ever conceived his Meaning otherwise ? But this Dictator, by his own Authority, will not only speak himself, but understand others to speak after his own Will and Pleasure : he assumes to himself (for who may forbid him ?) as a most expert Inventor of Words, to declare the Sense of his own Mind contrary to Custom ; and not content with that he also arrogates to himself the Power of interpreting the Opinions of others, contrary to common Consent and the most received Use. Σχέσις, when himself commands and permits it, ought to signify an Habitude ; but an Habitude Nothing, whatsoever most other Mortals say against it, when applying these Words to design their own certain Senses. Grammarians call the Agreement or Connexion of Nouns between the Substantive and Adjective σχέση ονομάτων. Divines dispute whether Images are to be worshipped σχετικῶς, i. e. for the σχέση or Relation which they obtain to the Originals they represent. Common Speech designs the Relations of Kindred and Affinity arising from a

(1) Pag. 45.

Conjunction of Nature or mutual Agreement by the same Appellation of $\alpha\lambda\epsilon\iota\sigma\iota\varsigma$. One might produce Waggon Loads of Examples, but the clear Testimony of one of the best Grammarians may serve. *Ἡ ἀλῆσις, i. e. Relation (says Suidas) is said of Things which are referred to another, as the Son to the Father, a Friend to a Friend: for these both relate and are related to one another. and therefore are termed ἀλῆσις Relations. Again Things are said to be related according to Comparison as lesser, greater, double, also Science and Sense. The Word ἀλῆσις then is not altogether insignificant and void of Sense, but notes something aptly enough, and is the same with Relation itself. (m) But I ask (says our Adversary) what is that which in this Place has, and what is that which is had? Is Reason called an Habitude because it has something or because it is had? If it have, what is it that it has, but if it be had, by what is it had? All which are trifling. To which I answer, when Reason is said by him to be a Relation, i. e. a Telling or Carrying again. I also ask what is that which there is carried or carried again, from whence or whither is it carried? But we have no Leisure for Trifling, in being strict and severe to gather the Significations of Words from their Etymologies alone, which are rather to be taken and approved from Custom and Consent, to which they only owe their Force and Power of signifying. Albeit since τὸ ἔχειν, i. e. to have is used innumerable Ways, nothing is more customary with Philosophers than by it to denote Relation and Respect. Aristotle in his *Categories*, The Essence of Relations consists in this πῶς ἔχειν that they have themselves in a certain Manner, or are in some sort affected, to something. And to have that Foundation true and real inti-*

LECT. XVIII. *Mathematical Lectures.* 335

mates what is had and found in the Terms of any particular *Relation*, by reason of which, or according to which, they mutually respect one another. *Ex. gr.* there is had (to answer our Adversary more fully) a determinate Quantity in the *Terms* of every *Proportion* by reason of, or according to which, one is compared with another; from whence is the Form of Speech used by Geometricians (not unobserved by himself) which explains the *Similitudes of Reasons* thus. As *A* has itself to *B*, so has *C* itself to *D*. Therefore *Euclid* is not out of the Way (he who has had the united Voice of so many Ages,) but his Censurer insolently wrangles; the former writes not insignificantly, but the latter reads carelessly; the former has a right Perception of the Nature of *Reason*, but the latter perverts his Explication of *Reason*; lastly, it is not *Euclid* that *coughs* but a certain Person that shamelessly boasts: One to whom it is indeed just to make Retaliation, and reprove with that Saying of *Euripides*.

— Ἐπεὶ τὰ μὴ καλὰ
λέγειν ἐπόλμας, πλῆθε ἢ τὰ μὴ φίλα.

*Since you have dared to utter Things unkind
Expect to bear unkind Things in return.*

But I trifle too much. I will only subjoin one Thing by the Way, that (n) *Nicomachus Gerasenus* in his *Musics*, by what Authority I know not, has *γένεις* for *Species*, and *λόγος* for *Genus*, changing the Order.

Secondly, After the Genus in defining Accidents, the Subjects come next to be considered, which are called *Terms* in *Relations*. Hence I take notice next that *Euclid*, applying this (o) Book to Geome-

(n) *Nicom. Mus. l. 1. p. 24.*

(o) *Μεγεθῶν.*

try, undertook only to define the *Reason* of Magnitudes. Hence it is there Magnitudes, instead of which, to make the Definition of *Reason* as general as possible, it ought to be *Quantities* or *Terms*. As it is in *Theon* (p) *Smyrnæus*, *Reason is a certain Habitude of two homogeneous Terms to one another, according to Analogy*, And (q) *Nicomachus* in his *Arithmetic*: *Reason is the Habitude of two Terms to one another*. But *Ramus* blames our Author for this, because he has defined the *Reason* of Magnitudes separately, since *Reason* agrees with all Things. *The Sophistry* (says (r) he) is perpetual through the whole Book of *Logic* and *Arithmetic* confined to the latter Subject concerning Magnitudes. I answer first, that a greater *Sophism* is committed by this Censurer himself, who confines *Reason* to Numbers, a Subject equally particular and less apt. (s) *Another Comparison of Quantity is conjunct with Numeration, and is called Reason, which considers how often the Consequent is contained in the Antecedent*. As if every Comparison of Quantity were subject to *Numeration*, and every *Reason* agreed with Numbers, or might be expressed by Numbers. It is sufficiently apparent, nor does himself deny but there are certain *Surd Reasons* and such as are inexplicable by Numbers; but there is no *Reason* at all which cannot be exhibited in Magnitudes of every Kind. Therefore *Number* is unsuitably assumed for the adequate Subject of *Reason*; and *Magnitude* is much more suitable, since there is no *Mode* or *Species* of *Reason* but what agrees with it. I answer secondly, since (as I imagine it has been abundantly proved) *Magnitude* is the principal and only Genus, properly so called, of *Quantity*; and others only by Rela-

(p) Cap. 19.
(r) Schol. 13.

(q) Lib. 2. p. 62.
(s) Arith. 2. 2.

tion, Participation, and Analogy, and consequently challenge the Attributes of Quantity only secondarily; and since the (t) Philosopher teaches us well, that the Reason of such Analogies requires that the Things which are primary are separately and in the first Place to be defined; hence the Reason of Magnitudes is deservedly first defined and separately; and nothing hinders but the Definition agreeing to it may be transferred analogically to the Reasons of other Quantities. And indeed whatsoever is truly attributed to the Reasons of Magnitudes and demonstrated by them, that agrees exactly to the Reasons of all Quantums; seeing all Quantums, as they have their own absolute Quantity, so they have a respective Quantity also consequently dependent on and to be determined by Magnitude. I answer *thirdly*, that the Author of the fifth Element did enough, if he openly professed only to expound the Nature of the Reasons of Magnitudes. Since (as we have insinuated) he proposed with himself to treat of these as confined to Geometry. This is usual with the Masters of all particular Sciences: Grammarians only describe Moods and Tenses, as significative for the Declensions of Verbs: Rhetoricians Tropes and Figures, not as they agree with all Things, but with Words and Sentences: The Moralist defines Virtues, not as the Virtues of Horses and Dogs (which *Plato* so often predicates) are comprehended in them, but such as relate to human Practice only: Musicians explain the Proportions and Spaces not of all Quantities, but of Sounds: and not to mention more, all particular Disciplines are wont to assume this Authority to themselves; they deduce, adapt, and confine the Significations they use to their own particular Consideration; they define

(t) *Met.* III. 2. VII. 4.

or describe the Terms they apply especially studying Perspicuity, and as much as may be Brevity, avoiding being compelled by another either to repeat any general Doctrine for the most Part separate from their Purpose, or to omit any Explication which may conduce for understanding what is said. But if this be not so exactly agreeable to the Laws of *Ramus's* Logic, yet it is not contrary to the Dictates of Reason itself, or worthy of Blame; for it is the utmost Injury to good Authors and the Arts themselves to act by the utmost Strictness from these, or any other Logical Prescripts. But it is one Thing to reduce the Whole of Philosophy into one Body, and another to treat of particular Sciences; in the former the Order of Things and an elegant Brevity, in the latter Clearness, Facility, Validity, are especially attended to, it being always of Moment to accommodate the Doctrine to the Capacity of the Learner. But I digress too far. Furthermore it may be answered with some that Magnitude may be so taken as to design every Quantity, by a very common Catachresis of that Word. For if Number, Weight, and Time be often said to be (*Magna*) great, why may not these Things as far as they are Quantities be called Magnitudes; and thus the Definition in the Elements may be extended to all Quantities? But enough has been said in the Defence of *Euclid* against the Opposition of *Ramus*. I proceed,

Thirdly to note, since even *beterogeneous Magnitudes* may some Way be compared together, or respect one another, according to something, *viz.* a Line may respect a Superfice, and a Superfice a Body as far as a Superfice may be applied to a Line as to its Side, and a Body to a Superfice as the Basis on which it stands; and as a Line is the Perimeter of a Superfice, and a Superfice encloses a Body, also a Line may be coextended with a Superfice

fice as to one Dimension, a Superfice with a Body as to two, and so far those may be compared with these: Also any sort of Comparison may be many Ways instituted as to the other common Affections, between such Quantities different in Kind; from which Comparisons notwithstanding, the Respects resulting are very different from this, according to which *homogeneous Magnitudes* are referred to one another in a manner which is here understood to be defined; therefore for excluding those whatsoever Relations there may be between *heterogeneous Magnitudes*, *Euclid* assigns the proper Terms of the Relation designed by it, and adequate Subjects of the Reason circumscribed within its Limits, by the Addition of (u) *Homogeneous*. *Homogeneous Quantities* alone are said to have *Reason*, because they alone are capable of Equality and Inequality, they alone admit of mutual Excess and Defect, and have the Properties adjoined to them subject to Geometrical Speculations. But we have treated enough of this before. Nor will I here dwell much upon *Ramus* blaming us with no shew of Reason: *That Reason*, says he, *of Equality and Inequality which Euclid proposes to define is common to all Things, a Line may be compared to a Superfice and a Body. Thus in the fourteenth Element, Bodies, Superficies, and Lines are compared together; so also Hippocrates's Lunula is squared, and oblique lined Angles are equal to rectilinear ones.* But who except this Censurer (that seems to catch at all Handles, and every where hunt for Occasions to abuse those ancient Masters of the Sciences, whom yet it were just not to reprehend without great Cause, and only where they manifestly are in the wrong; it would become us that are indebted to them for such great Inventions to act more mildly

(u) Ὁμογενῶν.

with them;) I say who, except this Censurer, thought that such *Comparisons* of Lines with Superficies and Bodies as are handled in the fourteenth Element do pertain to the Nature of *Reasons*? When it is investigated how the Sides of a Pentagon or Decagon, of a Pyramid or Octoedron are so affected to one another, or towards the Radius of the Circle or Sphere in which these Figures may be inscribed; who ever thought that these Right Lines or Sides of the Figures are compared with the Figures themselves as to *Reason*? I believe none are so ignorant: Yet *Ramus* means so, or he means Nothing to the Purpose; at least as far as I can perceive he can understand nothing else. Also who ever thought, that the Lunula of *Hippocrates* is a plane Figure terminated by a Square, or *heterogeneous* to every other plane Figure, that being supposed? Why could he not by a like Reason have produced a more obvious Example by comparing a Sphere with a Cone or Cylinder, *i. e.* a Body comprehended in one round Superfice, with a Body contained in a mixed Superfice? He is unwilling to understand what is *homogeneous* and *heterogeneous*, at least what Geometricians continually signify by these Words; he is unwilling to distinguish *Homogeneity* and *Heterogeneity* from *Similarity* and *Dissimilarity*. But I pass from hence and note,

Fourthly, that since even *homogeneous Magnitudes*, as to many of their Accidents, may be compared (suppose as to some of their particular Properties, *viz.* their Situation, local Distance, or diverse Qualities; I add, with the ancient Scholiast, also as to Value or Price;) *ex. gr.* two Lines as to Rectitude or Curvity may be to one another *Similarly* or *Dissimilarly*, one may be at Hand, the other twenty Furlongs distant, one may be White, the other Black; yet since none of these Relations can
be

be signified here, setting these apart, here is adjoined (x) *according to Quantity*, signifying the Foundation of this Relation. For the Foundation is next to be subjoined which ultimately compleats its *formal Reason*, and what the Logicians call its *Essential Difference*, for explaining the Nature of the Relations after the Genus is expressed, and the Terms lawfully constituted. *According to Quantity, i. e.* according to the Determination of its Magnitude, or the determinate Magnitude itself, at least as far as it is asked how great Things are, and the Answer is made *so great*, by which he seems to signify nothing but the Magnitude itself, as it is determined in itself by its own Singularity (if I may so speak,) and is distinguished from other Quantities. Now the Cause by which a Magnitude, or rather a *Thing great* (for generally concrete and abstract Terms are confounded,) is such a Way referred to another, is conceived to be Nothing but absolutely the having so great a Magnitude in itself, as universally every *Relation* is founded in *something absolute*. Therefore I do not well approve of that Exposition of some, that *according to Quantity* means, according as one Thing is so many fold of another, or *according to Tantuplicity*; for they stick not to coin such Words, signifying I do not know what by them. For besides such a Definition (*ex. gr.* of a *double Reason to be the Relation of two Quantities according to Duplicity*) sounds not well, *Tantuplicity* seems intrinsically to contain or denote a certain Relation; but the Foundations of Relations are not Relations, but are Things absolute because of, or according to which the Terms of the Relations are referred to one another. I suppose it would be wrong to say, This is similar to that, because it

(x) Κατὰ πηλικότητα.

is similarly affected; but right because it is hot or white, or by Reason of the absolute Qualities Heat and Whiteness: so also this is said to be equal to that, because of, or according to the absolute Magnitude of each, and because of the same, this is said to be so many Times that. Nor for the same Cause do I like that Interpretation of *Clavius*. *According to Quantity, i. e. according as one is greater than another, or lesser, or equal.* Equality, Majority, and Minority are not Terms also relative, nor consequently fit for founding a Relation. Moreover when *Reason* is defined, *Equality, Majority, and Minority* (as being comprehended under their Reason or Genus) are themselves defined in Part and virtually. From whence they seem not to be well placed in the Definition of Reason itself. Yet I do not dislike, nay I think the Observation very good, which is made by the Greek Scholiast who thinks it designedly put *according to Quantity*, rather than *according to Quotity*, because all *Reasons* are not capable of being expressed by Number, nor is every Quantity so many Times another in any comprehensible Manner. According to him, *Euclid* would not found the Reason of *Quantums* in their *Quotity* or *Quotuplicity*, because every Quantum is not a Quantum of another, *i. e.* it does not contain, nor is contained in, another so many Times, either perfectly or imperfectly according to itself, or to any of its aliquot Parts; but *according to Quantity*; because every determinate Quantum has a Quantity in itself according to which it may be compared with another determinate Quantum.

But it is objected against this Definition so explained that it equally agrees with the *Relation of Quantums* which intimates their *Difference*. For that also is truly called a *Relation* of two *Quantums* of the same Kind *according to Quantity*. I
answer

answer *first* that when it is here said *according to Quantity*, it is understood according to the Quantity of the Terms themselves. But the *Relation intimating Difference* seems not to be founded in the Quantity of the Terms compared, but in the Quantity of some third, *viz.* of the Excess, or of the absolute Quantum whereby the Antecedent exceeds or is short of the Consequent; *ex. gr.* the Relation between 10 and 8 seems to be founded in the Quantity of *Two* and not in the Quantity of the Numbers 10 and 8. For that Term alone (*viz.* the Number *Two* represented) sufficiently indicates and expresses that Relation; but a *Geometrical Reason* cannot be expressed but by two Terms expressed, or at least understood. This that most learned Man acknowledges in his Dispute against *Meibomius*. *We say indeed* (says he) *that that Difference is not an Arithmetical Reason properly speaking, or even the Essence of that Reason, but the Foundation of that Relation which is called Arithmetical Reason.* By which Saying he solves his own Exception against *Euclid's* Definition explained after our Manner. And *Aristides Quintilianus* seems to have observed this, when he distinguishes the Geometrical and Arithmetical Considerations of Quantities thus. *Geometrical Reason compares two unequal Quantums, i. e. the Whole and the Part, according to their Quantities; but Arithmetical Reason, which regards the Differences of unequal Terms, considers the Consequent Term and the Excess as Parts of the Antecedent.* But I answer *secondly*, that perhaps *Euclid* with others of the Ancients before recited were not acquainted with the *Arithmetical Relation* of Quantities, at least thought that there was no such Reason taken notice of by Geometricians. For the Consideration of that Relation seems to suffice for the Dimensions of Quantities, and other Determinations as to Species and Situation, which are

the principal or only Scopes of a Geometrician. Nor does the very Vulgar hardly conceive any other Relation of Quantities: For when Men commonly ask how much this or that is, they only enquire how often it contains some stated Measure similarly known to us, or how often it is contained in it, *i. e.* they seek a *Geometrical Reason* to this Measure of it. I adjoin *thirdly* that *Relation according to Difference*, when it is expressed by a Number denominating any of the Terms compared, it scarce differs in reality from *Geometrical Reason*. As when I say B exceeds A by 3 A, it is all one as if I said B is four times A, or is referred to A as 4 to 1. Or if I should say B exceeds A by one third Part of B, it is all one as if I said B is three halves of A, or is to A as 3 to 2. And perhaps they have an Eye to this, who say that (*y*) *Reason consists in the Difference of two Quantities compared with either Quantity*; which way of speaking notwithstanding is very difficult and obscure in itself, and productive of most grievous Errors; as may be seen from the Disputation of that learned Man against *Hobbs* and *Meibomius*; whose Methods therefore of explaining Reasons I neither approve nor defend. However, I say, the *Relation of Quantities as to Difference*, if at any Time it is considered by Geometricians for determining the Measures of Quantities, it for the most part intimates the same with *Geometrical Reason*, as applied by them. Wherefore *Euclid* neglected it, either as useless, or no way different from *Geometrical Reason*.

But I proceed to observe *fifthly*, that the (*z*) Words *to one another* in the Definition are commonly interpreted to signify a certain Reciprocation,

(*y*) *Hobbs de Corp.* c. 11. §. 3, 5. c. 12, §. 8. c. 13. §. 1.

(*z*) Προς ἄλληλα.

and

and alternate Permutation of this Relation, by such a Transposition of the Terms, that sometimes the Antecedent may be the Consequent, and the Consequent the Antecedent; which Interpretation I do not think to be good, as making the Definition itself absurd. For if the Comparison be inverted or changed by the Transposition of the Terms, there will arise two Relations very different from one another. As *ex. gr.* the Relation of a Line of three Feet to a Line of one Foot is the Relation of three to one, or a triple Reason; but inversely, the Relation of a Line of one Foot to a Line of three Feet is the Relation of one to three, or a subtriple Reason; one of the Numbers denominating which Reasons is nine times the other. $\frac{1}{3} = \frac{1}{9} \times 3$. Therefore I rather chuse to interpret *To one another*, to mean *One to the other*. For without doubt he aimed to define, or certainly ought to define, one simple Reason of one Magnitude to another, not two inverted Reasons to one another. But because it is no Matter in this Comparison whether Magnitude supply the Place of the Antecedent, or whether of the Consequent (forasmuch as every Magnitude indifferently obtains some Reason to every other homogeneous Magnitude,) therefore he put *to one another* to signify an Indifference, as to the Situation and Order of the Terms. If any two homogeneous Magnitudes were compared together as to Quantity, whatsoever Antecedent be supposed its Relation to the other is called *Reason*. Nor does the Word *ἀλληλον* even taken in the utmost Rigour of its Original Notion refuse but rather favour this Interpretation, as signifying *ἄλλο ἢ ἄλλο*, i. e. *One or another* disjunctively; and not *ἄλλο καὶ ἄλλο*, i. e. *One and another* conjunctly. But I forbear to criticise any longer.

There

There remains in the *Sixth* Place only the Word (a) *Certain* to be examined, a *certain* (b) *Habitude*, Which Interpretation a certain great Mathematician of our own Country dislikes, suspecting I know not what abstruse Myſtery to lie hid under the Adjective ποιᾶ . For *certain* (c) he would rather have ſubſtituted *qualitative*, i. e. as himſelf explains, (d) *which belongs to the Predicament of Quality*, becauſe *Reason* determines the Species and Quality of Figures with the Indication or Situation of their Parts. But he rejects the vulgar Interpretation, becauſe the Word ποιός always cuſtomarily reſpects *Quality*, nor does it here ſo much intimate a *certain* as a *certain Species*, or rather a *qualitative Habitude*, which belongs to the Predicament of *Quality*. To which he ſubjoins, *And indeed in an accurate Definition it is by no means excuſable, for Reason to be indefinitely defined a certain Reason, but it is to be determined what ſort of a Relation it is.* Farthermore ſince it might be answered that the Relation is ſufficiently determined from what goes along with it, eſpecially from the adjoined Condition according to *Quantity*; he denies that this is ſufficient, becauſe there is another Relation juſtly belonging to *Quantity*, viz. the ſo often mentioned *Relation according to Difference*, which yet as he thinks is not ποιᾶ ῥείσις a *qualitative Habitude*. But I can't notwithſtanding be eaſily brought to believe that this ſubtle Exposition is agreeable to the Sentiment of *Euclid* himſelf. For firſt it is ſomething hard for ποιός to ſignifie *belonging to Quality*, or rather *effective* or *determinative of Quality*, according to the Sentiment of that moſt learned Man himſelf. Indeed with *Ariſtotle* and others ποιός is every where of the ſame Signification with ſome Sort of

(a) Ποιᾶ .(b) Ποιᾶ ῥείσις .(c) *Arith. c. 25. contra Meib. 7.*(d) *Ἐαυτότητι. p. 60.*

endowed with *some sort of Quantity*, (as that which is affected with any sort of Habit, Power, or Passion is by him denominated ποιός τις) but no where, I believe, with *Qualificative* which had been better denoted by ποιωτική and more agreeable to his own Exposition than *Qualitative*: for ποιῶν signifies to *make or render sub.* Therefore he has attributed to our Author a Manner of Speech sufficiently improper, unusual, obscure, and consequently incongruous to the Laws and Nature of Definitions. I add that it seems sufficiently remote from the intrinsecal Nature of *Reason*, and only accidental to it, that it sometimes conduces to determining the Species and Quality of Figures. It is not considered in Figures only, but often without them, nor is it otherwise subservient for their Determination than by first determining the Quantities of certain Magnitudes, viz. of the Lines or Superficies by which they are included. It does not then seem likely that our Author here regarded Definitions, since Definitions ought only to contain such Attributes of Notions as are necessary, universal and primary. And as to the Predicament of *Reason*, it pertains simply to Relation; but, because of the Comparison of the Terms which are always Quantities, may respectively be reduced to Quantity, and rather because of its own Foundation, which is some absolute Quantity, as is said above. It is vulgarly reckoned among the Properties of Quantity that by it Things are said to be equal and unequal, i. e. one is equal, double, triple, &c. of another, or affected with such a *Reason* towards another. Therefore *Reason* is rather a *Quantitive Habitude*, as *Similitude* is wont to be called a Relation in Quality or *Qualitative Relation*, because it is founded in some Quality. But if I am not mistaken it would sound ill to most Ears to be called a *Qualitative Relation*

tion according to Quantity, therefore Quantitative is better than Qualitative. Moreover there are innumerable Examples among the ancient Mathematicians that the Word ποῖός does not always design a Quality properly so called, even in Definitions, as is pretended, but oftner a mere Particularity, i. e. an indefinite Restriction of a general Word; the same Way, as when Man is defined a certain Animal endowed with Reason, where certain only intimates that the Name Man is contained under the Name Animal confusedly and indistinctly, assigning no certain Limits, and is not perfectly adequate, to it. Thus (e) Theon defines Analogy to be ποῖὰ ῥέσις a certain Habitude of Reasons to one another; and not as I suppose, a qualitative Habitude, for what Quality intervenes in that Place? Aristides (f) Quintilianus defines the Genus of Music to be ποῖὰν διαίρεσιν a certain (not a Qualitative) Division of a four stringed Instrument: For a four stringed Instrument may be innumerable Ways divided, yet all these Kinds of Divisions do not constitute the Genus of Music, but some certain only; viz. one Kind is Diatonic, another Chromatic, a third Enharmonic. To which agrees Euclid, the Genus, says he, is ποῖὰ διαίρεσις, i. e. a certain Division of four Sounds. And the same Aristides, It is from Sounds and Spaces having ποῖὰν τάξιν a certain (not a qualitative) Order. Nicomachus in his Enchiridion defines a musical Space or Difference to be ὁδὸν ποῖὰν a certain Passage from Flat to Sharp, or the contrary. And such is the Definition of Thrasyllus. A Space or Difference is a certain Habitude of Sounds to one another: Where it is to be noted that the Arithmetical Reason, or Difference which is between two harmonical Sounds is precisely called ποῖὰ ῥέσις a certain Habitude:

(e) Cap. XXI.

(f) Page 16.

which the learned Man acknowledges to be only a *Quantitative Relation*, and reckons that a *Geometrical Reason* in Contra-Distinction to it is termed ποια ἁέσις, i. e. a *qualitative Relation*. But because such indefinite Words are thought not fit to be suffered in accurate Definitions, we must affirm that however the best Authors have admitted such. And besides those just now appealed to, I will cite *Euclid* for one, who in his *Isagogetharmomics* inserts the Word τις in the two next contiguous Definitions, *A Tone*, says he, is τόπος τις a *certain Place of the Voice capable of Conjunction with another, without Latitude*. And again *Mutation* is the Translation ὁμοίᾳ τινός of *some like into an unlike Place*. He refused not, nor indeed in my Opinion ought he to refuse, such Words. For in every Predication of a more extensive Word concerning a narrower, or of a more general Word concerning a more special, if some Restriction be not expressed, at least it is tacitly understood. As when it is said *a Man is an Animal*, it is understood a *certain Animal*, and that which is understood in the direct Proposition is expressly pronounced in the converse *a certain Animal is Man*. But that which is always understood can never be expressed without Blame, wherefore I see not why such Definitions as these ought to be disliked, *A Man is a certain Animal endowed with Reason*; *A Triangle is a certain plane Figure comprehended within three Right Lines*; *Reason is a certain Relation of homogeneous Quantums according to Quantity*. But he thinks that this last Definition vulgarly taken agrees as well with *Arithmetical Reason*, from which notwithstanding it ought to be distinguished: to which it was answered by Way of Anticipation, when we endeavoured to explain what is meant by being referred according to *Quantity*.

I will

I will only now add, that perhaps in delivering this Definition *Euclid* designed nothing else but a Prelude for Method or Ornament's sake to those more accurate Definitions of *the same*, a *Greater*, and a *Lesser Reason*, anon to be subjoined, that he might insinuate a certain general Idea of *Reason* into the Minds of the Learners by this *Metaphysical* Definition: I say *Metaphysical*, for it is not properly *Mathematical*, since it has no Dependence upon it, nor is, or I believe can be, deduced in the Mathematics. Of which sort also may this Definition of *Analogy* be reckoned. *Analogy is a Similitude of Reasons*, which can be servicable for no Mathematical use, nor I think is proposed for any other End, but that by it some general confused Notion of *Analogy* may be in-filled into the Minds of Learners. And the whole Doctrine of Reasons, the whole Business of Mathematics depends upon the accurate Mathematical Definitions afterwards subjoined by him; to those therefore we ought especially to attend, by these the Doctrine of Reasons is perfectly explained; and these and the like cannot at all be omitted without a remarkable Detriment to the Mathematics: as we may see in the seventh Element, where the *Analogy of Numbers* is defined and treated of; yet without applying any Definition of *Reason* agreeable to *Number*, though such a Definition was as requisite and useful there, as here; but the Necessity in neither Place was great. Albeit I do not believe that a Thing in itself so general and abstract, and therefore more difficult to be conceived and explained, is capable of a more commodious Definition than this which *Euclid* has assigned, which I therefore thought fit to explain more fully, and vindicate against the Cavils of Opposers. Where I now fix my Foot, designing in my next Lecture to proceed to the Species, and more especial Properties of Reason.

LECTURE XIX.

Of the Species and Differences of Geometrical Reason.

WE have in Part delineated the Nature of *Geometrical Reason* by explaining and vindicating its Definition assigned in the *Elements*. Which might have been otherwise declared by saying more generally and confusedly, but perhaps more agreeable to a common Capacity, that *Reason is the determinate Way or Manner whereby any one Quantity contains, or is contained in, another, which is the same, or very like to that Way or Manner according to which one Quantity is said to be so many Fold of another, or to contain another so often, or to be such a Part or so many Parts of another, or to be contained so often in another: which Manner is easily comprehended, when the Quantities compared can be expressed in Numbers; as the Manner, whereby a Pound Troy contains an Ounce, signifies no more than that the former contains the latter twelve Times, or is to it as 12 to 1; whence a Pound is said to obtain a Duodeuple Reason to an Ounce: The Manner whereby a Foot in Length is contained in a Geometrical Pace is that the former is the fifth Part of the latter, or is to it as 1 to 5, which is signified by saying, that the Reason of a Foot to a Pace is subquintuple: Which Manner is expressed by the abstract Word Quintuplicity or Quintuplity. But when the Quantities compared, as to their absolute Quantity, are such as cannot be perfectly expressed,*

pressed, at least they may be understood in Numbers ; because that contains, or is contained in this, after some *determinate Manner*, otherwise than it contains, or is contained in, any other Thing unequal to this ; therefore this *Way* or *Manner of containing* is very like that, whereby the Quantities denominated by Numbers respectively do contain, or are contained in, one another, and may always be nearly expressed in Numbers simply, and on the Part of the Thing. As *ex. gr.* when the *Reason* of the *Periphery* of a *Circle* to its *Diameter* (though not exactly and perfectly known) is represented by saying that the *Periphery* by *Apposition* is *triple* and *sesquiseptimal*, *i. e.* contains the *Diameter* three times and one seventh Part of it nearly. So also the *Reason* of the *Diameter* to the *Side* of a *Square*, which the Nature of the Thing will not admit to be precisely expressed in Numbers may yet be represented approaching the Truth, by saying that the *Diameter* is to the *Side* as 1.4 to 1, or more nearly as 1.41 to 1, or yet again more nearly as 1.416 to 1, &c.

But we will endeavour farther to illustrate the Nature of *Reason*, by exhibiting *first* its *Species* and *Differences* ; for the Comprehension of the *subjected Species* conduces very much to a perfecter Knowledge of the *Genera* or *Kinds*, the *Genera* themselves being constituted and as it were generated from the Argument of these as to some essential Property : then *secondly*, by exhibiting certain *primary Accidents* of *Reasons* (expounding their *Comparisons* to one another, *Composition*, *Continuation*, *Addition*, *Subtraction*, *Division* and *Reduction*) also in the mean Time examining, by the Way, some controverted Questions, which do not a little contribute to the Illustration of this Subject.

As to what pertains to the *Species* of *Reason*, its *first* Division most naturally follows the different
Affection

Affection of the *Terms* in this Manner: the *Antecedent* of the *Reason* is either *greater* than the *Consequent*, *Equal* to it, or *Lesser* than it, hence arise *three Species* of *Reason*: The *Reason* of *Greater Quantity* to a *Lesser*, of an *Equal* to an *Equal*, and of a *Lesser* to a *Greater*; commonly called a *Reason* of *greater Inequality*, of *Equality*, and of *lesser Inequality*; but they may be more simply and concisely named *Majority*, *Equality* and *Minority*, and by these Names for brevity's sake we will always design them. But some stile *Majority* and *Minority*, the *Reason* of *Excess* and *Defect*, which Words also we will perhaps sometimes use. And that *double Dichotomy* according to (a) *Nicomachus* comes to the same Thing, when *Reason* is first divided into *Reason* of *Equality* and *Inequality*; and *Reason* of *Inequality* again subdivided into *Reason* of *greater* and *Reason* of *lesser Inequality*. The Thing is too plain of itself to be illustrated by Examples; yet we will give one: For Instance, the *Reason* of a Pound Troy to an Ounce (or of the Number 12 to 1) is a *Majority*, or a *Reason* of *greater Inequality*, or a *Reason* of *Excess*, because the *Antecedent* is greater than the *Consequent*. The *Reason* of a Quarter of a Pound Troy to three Ounces is a *Reason* of *Equality*, because the *Antecedent* is equal to the *Consequent*: But the *Reason* of an Ounce to a Pound is a *Minority*, or a *Reason* of *lesser Inequality*, or a *Reason* of *Defect*, because the *Antecedent* is lesser than the *Consequent*. These by the (b) *Greeks* are sometimes called *greater*, *equal* and *lesser Reasons*, but improperly; for these Words do more frequently and properly design the *Respects* of the *Reasons* themselves compared together, and not the *Species* of *particular Reasons* absolutely taken. For instance, in comparing the *Rea-*

(a) *Nicom.* lib. 1, p. 24.(b) *Theo.* Smyr. cap. 22.

sons of nine Ounces to four Ounces, and of eight Ounces to four Ounces ; the Reason of nine Ounces to four Ounces is *greater* than that of eight Ounces to four Ounces, *i. e.* the Reason of 9 to 4 is *greater* than that of 8 to 4. But the *Reasons* of nine Ounces to four Ounces and of eight Ounces to four Ounces simply referred to one another, are not rightly stiled *greater Reasons*, but *Reasons of Majority, Excess,* or *greater Inequality*, *i. e.* *Reasons of greater Quantities to lesser Quantities.* This is the first Division of Reasons.

Otherwise *Reason* (or *Reason of Inequality*, for it matters not whether *Reason* univerfally, or *Reason of Inequality* particularly, be fo divided) otherwise, I fay, *Reason* is divided by refpecting thofe *Properties* already explained in Part, which I call *Commensurability* and *Incommensurability*. For becaufe fome of the Terms compared together are *commensurable*, *i. e.* are capable of being meafured, compleatly divided, or quite exhausted by the fame Quantity taken once or oftner, and confequently of being accurately expreffed in Numbers ; while others are *incommensurable*, *i. e.* are meafurable by no common Meafure, have no Part aliquot to the fame, and confequently, being fo affected cannot be expreffed or perfectly reprefented by any Number : Hence arifes the Division of *Reason* into *Effable* and *Ineffable*. Where notwithstanding it is to be noted that thefe Words $\rho\eta\tau\acute{o}\varsigma$ *effable*, and $\acute{\alpha}\rho\eta\tau\acute{o}\varsigma$ *ineffable* are very often ufed in the Elements. For when *Euclid* confidered that, any Right Line being expounded (which he calls *effable*, as being denominable or effable by any Number at Pleafure,) the Lines compared with it are of three Kinds, *viz.* fome are *Commensurable* with it in Length, others are *Incommensurable* in Length, yet fo that their Squares are commensurable, and capable of being denominated by Numbers moft perfectly exhibiting their
their

their true Reasons to the Square of the Line expounded: Lastly, most others are not only *Incommensurable* to the Line expounded in Length, but also in Power, *i. e.* their Squares are also *Incommensurable* to the Square of the Line expounded: I say, when *Euclid* considered this, he named the Lines of the two former Kinds *Effable*, as capable of being some Way expressed; but the last Kind he called *Irrational* or *Ineffable*, as being no Way explicable, or capable of being expressed, by Numbers. Therefore according to *Euclid* some *Incommensurable Quantities* seem to have an *Effable Reason* to one another (for if the Quantities themselves are said to be *effable*, consequently their Reason will be *effable*) I say Quantities incapable of *Commensurability* in Length, Breadth or Thickness may have an *Effable Reason*; for albeit their Reason cannot be *immediately* represented by any common Numbers, yet it may in Part be so *mediately*, *viz.* by the Intervention of their Squares, when these are truly denominated and expressed in Numbers. For from thence they may be called the *Sides* or *Square Roots* of such Numbers; at least such an Expression suffices for determining their relative Quantity, and causing that the Quantities themselves may be both in some Measure subjected to our Estimation and easily capable of real Representation. But with some it seems most agreeable to Reason to have the *Reasons of Incommensurable Quantities* called *Ineffable*; because the Terms of such *Reasons* cannot properly and immediately be expressed in Numbers vulgarly known and received, and therefore we will retain this Sense; though the most learned *Borellus* (perhaps for avoiding Ambiguity) chuses to divide *Proportion* into *Commensurable* and *Non-mensurable*, devising new Words, and such as in my Judgment are not very suitable. For the *Proportions of in-*

commensurable Quantities are *mensurable*, as well as the *Proportions* of *commensurable Quantities*: and in my Opinion he had spoke more accurately if he had said *Proportion* is either of *Commensurable Quantities* or *Incommensurable Quantities*. But of these Things by the by, let us return to the proposed *Species of Reasons*.

An *Effable* or *Explicable Reason* is that which may be really expressed in common Numbers, *i. e.* in Integers, mixed Numbers and Fractions; or rather always in Integers, because every *Reason of Numbers* however fracted or composed of Integers and Fractions may be always reduced to Integers by multiplying by the Denominators of the Fractions. Examples may be taken from all Measures of the same Kind, such as a Finger's Breadth, a Span, a Palm, a Foot, a Cubit, a Yard, an Ell, a Pace, a Furlong, a Mile, a League for measuring Intervals of Longitude; a Grain, a Dram, an Ounce, a Pound for estimating Weights; a Farthing, a Penny, a Shilling, a Crown, a Mark, a Pound for computing Money; a Minute, an Hour, a civil Day, Month, Year; I say, civil, because it cannot be known whether these natural Parts of Time are commensurable or no. These Quantities and the like have their *Reasons* to one another *Effable* or *Explicable*, and are therefore suited to vulgar Uses. For Instance the *Reason* of a Mark to a Pound is *Effable*, because they are expressed by the Numbers $\frac{2}{3}$ and 1 or 2 and 3, or any other Number which are sesquialter to one another. So also the *Reason* of a Shilling to an half Crown is expressed by the Numbers $\frac{2}{5}$ and 1 or 1 and $2\frac{1}{2}$, or 2 and 5; which *Reason* is said to be *sub-multiple-double-sesquialter*, as we will shew anon.

An *Ineffable* or *Inexplicable* (or as some call it *Irrational*) *Reason* is that which is between *Incommensurable Quantities*, whose Reason cannot be perfectly

perfectly expressed by any true and vulgar Numbers whatsoever. Such is the *Reason* in that most trite Example of the Diameter to the Side of a Square ; for no two Numbers can be found in the whole Series of possible Numbers (integral, fracted, or mixed) whose *Reason* does exactly represent the *Reason* between these two Quantities. For since the Square of the Diameter (as is demonstrated in the Elements) is twice the Square of the Side, and there are no two Square Numbers the one double the other, in the whole Series of common Numbers, therefore there are no Numbers which can exhibit the *Reason* of the Diameter of a Square to its Sides. And innumerable such *Reasons* are found in all Kinds of Quantities, so that comparing together regular Figures, as well plane as solid, inscribed or circumscribed, in the same Circle or Sphere ; scarce any will be found to have a *Reason* to one another *explicable* in Numbers, either as to their Sides or Perimeters, or as to their Areas, or as to their Solidities. Whence that the *Reasons* of these and most other Quantities may be some Way referred to Numbers (as being the most general, most known, and most commodious Symbols of Quantities) it was necessary to devise those Numbers called *Surds* or *Irrationals*, that the *Reasons* of these Quantities may be some Way expressed. And of these *ineffable Reasons* there are reckoned no *Species*, because the different Ways whereby their Terms contain, or respect, one another, cannot be well conceived to be distinguished, and no Method is yet invented for expressing them otherwise : But I will endeavour to reckon up the *Species* of the *Reasons* commonly called *Effable*, and explain them as briefly as I can. For why should I dwell upon Things sufficiently clear of themselves ? It is rather my Design to offer those Things to your Consideration, which seem less common and more

intricate, every where passing lightly over such Things as are obvious and plain.

Nothing, in the *first* Place, is more manifest than that the *Reason* of equal Quantities is always *Effable*, as being capable of Expression by any equal Numbers whatsoever. *Ex. gr.* Every equal Quantity is to every other, as One to One, or Two to Two. Therefore the *Reason of Equality* may be said to be the *first Species* of *Effable Reasons*. And since the *Reason of Inequality*, as we have seen, is twofold, *viz.* of *Majority* and *Minority*, or the *Reason of Excess* and *Defect*, there are vulgarly *five Species* of *Effable Majority*, to which there answer universally just as many *Species* of *Minority*. These we will recount and expound, yet so as first to investigate the Foundation and Original of this Division, which ought especially to be regarded in every technical Division. And this we undertake to do by noting that when we compare two Quantities, whose *Reason* to one another is *Effable*, or in their Stead the Numbers whereby they are represented, *i. e.* when we seek the *Manner* whereby the Antecedent contains, or is contained in, the Consequent, we attempt to represent this *Manner* in Numbers as small as possible; because every *Reason* is more easily estimated and comprehended in the *least Terms*. Therefore we endeavour that one of them, *viz.* the Consequent be Unity, the lowest and most simple of Numbers, which being laid down, we seek an Antecedent Term to Unity agreeing with the Consequent. And *that* Term of the *Reason* to be estimated is called the *Denominator*, as denominating and expressing it most suitably to our Capacity. But because such is the Nature of Arithmetical Division that as often as the Number to be divided contains the Divisor, the Quotient found contains Unity; therefore that Denominator

minator (or Antecedent of the Reason whose Consequent is Unity) is found by dividing the Antecedent of the Reason proposed by the Consequent. Moreover, since that *Denominator* or Quotient, because of the *intrinsic Diversity* of the Terms themselves, may be a Number of a different Species (*viz.* Integer, fracted, or mixed, and not the same Kind of Fraction or mixed Number) *ex. gr.* by considering the *Reason of greater Inequality*, the said Quotient found by the Division of the Terms may be either an Integer, or Unity with a Fraction whose Numerator is Unity, or Unity with a Fraction whose Numerator is greater than Unity, or an Integer greater than Unity with a Fraction whose Numerator is Unity, or lastly an Integer greater than Unity with a Fraction whose Numerator exceeds Unity. From these *five various Ways* or *Species* of the said Quotient arise five Species of *Effable Majority*, which are vulgarly called *multiple*, *superparticular*, *superpartient*, *multiple-superparticular*, and *multiple-superpartient*; to which answer the *Reasons* of *Minority* named *submultiple*, *subsuperparticular*, *subsuperpartient*, *submultiple-superparticular*, and *submultiple-superpartient*: which we come now to illustrate in their Order.

First, The Reason of one Term to another is said to be *multiple*, when the Antecedent exactly contains the Consequent any Number of Times more than once; or when the Consequent perfectly measures the Antecedent, so as to leave no Remainder. Or which is the same Thing, when the Consequent is any Aliquot Part of the Antecedent, which being taken some Number of Times totally composes, equals, or compleats the Antecedent; and consequently the *Denominator* of this *Reason* is always an *Integer*. Thus a Geometrical Pace is to a Foot in a *Multiple Reason* denominated

by the Integer 5 ; because a Foot taken five Times exactly makes a Pace ; or because a Pace includes a Foot five Times without a Remainder. Hence it is apparent that this *Reason* has as many *subordinate Species* as there are Integers by which they may be denominated, and distinguished which are infinite : *Ex. gr. Double, Triple, Decuple, Centuple, Millecuple, &c. Reasons* are *Species* of *Multiple Reason*. *Submultiple Reason* therefore, which answers universally to *Multiple*, is when the Antecedent exactly measures the Consequent, is an Aliquot Part of it, or is contained in it some Number of Times ; and its Denominator is always some simple Fraction, whose Numerator is Unity. Thus a Foot to a Pace is in the *submultiple Reason*, as being five Times contained in a Pace, and having for its Denominator the Fraction $\frac{1}{5}$. In like Manner this Kind of *Reason* has as many *Species*, as there can be simple Fractions denominated by any Number, whose Numerator is Unity : *Ex. gr. subduple, subtriple, subdecuple, subcentuple, &c. Reasons* are *Species* of *submultiple Reason*. For since these *Reasons* cannot fitly be signified by Words of common Use, therefore Mathematicians design them by prefixing *sub* to the Names of the *Multiple Reasons* inverted. For the Words *Second, Tenth, Hundredth, Thousandth* (by which are expressed the Aliquot Parts of Unity) cannot be so fitly applied for denoting these *Reasons*, because they are moreover ordinal, and do not only signify a Division into Parts, but also a certain Place of Things disposed in some Order : as the *third King from Romulus*, the *eighth of the Wise Men*, the *hundredth Year hence* : Otherwise I do not see but the *Third, Fourth, Tenth, &c. Reasons* might serve for denoting these *Reasons*, as well as *Double, Triple, Decuple, &c.* for the *Species* of *Multiple Reasons*. It appears then that the Correlative Terms *Whole* and

Part

Part are common to both *multiple* and *submultiple* Reason, by taking the Word *Whole* according to its native Signification and the Word *Part* for an Aliquot Part according to *Euclid's* Sense and Definition. *A Part is a Magnitude of a Magnitude, a less of a greater, when the less measures the greater.* But I proceed to other *Species*.

Secondly, A Reason is said to be *superparticular* when the Antecedent so exceeds the Consequent that some Aliquot Part of the Consequent remains over and above, whence the Reason of the Name: Or when the Antecedent includes the Consequent no oftner than once, and some one only Aliquot Part of it besides: Or when the Antecedent divided by the Consequent exhibits Unity for the Quotient, with Unity also remaining yet to be divided by the Consequent: and consequently the Denominator of this Reason is Unity with a Fraction annexed, which has Unity for its Numerator. Such is the Reason of a Cubit to a Foot, because a Cubit exceeds a Foot by one half of a Foot; so also 9 Ounces is in a *superparticular Reason* to 8 Ounces, because 9 Ounces contains 8 Ounces once and an eighth Part of it more, or because $\frac{9}{8} = 1 + \frac{1}{8}$. The *Species* of this Reason are also infinite, according to the infinite Multitude of Denominators; which in Latin use to be signified distinctly by prefixing the Particle *sesqui* to the Names of the Ordinal Numbers, as *Sesquialtera* (or *Sesquiseconda*) *Sesquitertia*, *Sesquiquarta*, *Sesquidecima*, *Sesquicentesima*, &c. which Words must be thus understood, *viz.* when the Antecedent exceeds the Consequent by its half (as 12 exceeds 8) that is said to be the *Sesquialtera* of this; when by one third (as 12 exceeds 9) *Sesquitertia*, &c. The Inverse of *Superparticular Reason* is called *Subsuperparticular*, and its *Species* *Subsesquialtera*, *Subsesquitertia*, *Subsesquidecima*, &c. The Nature of which *Reasons* sufficiently appears by

by comparing them with their Opposites ; for they differ from those only by a Transposition of the Terms, and their Denominators are to Unity, as Unity to the Denominators of their inverse Reasons. Concerning which we will yet remark this, that the Denominator of a *Subsuperparticular Reason* is always some Fraction whose Numerator is an Unit less than the Denominator. Thus the Denominator of a *Subsesquialter Reason* is $\frac{2}{3}$, of a *subsesquiterce* $\frac{3}{4}$, of a *Subsesquiquart* $\frac{4}{5}$, &c.

Thirdly, we proceed to a *Superpartient Reason*, which is when the Antecedent exceeds the Consequent by some Aliquot Parts more than one, whence the Name : Or when the Antecedent includes the Consequent once, and some aliquot Parts of it more, I say Parts to distinguish it from a *Superparticular Reason* : Or when the Antecedent divided by the Consequent exhibits Unity for the Quotient, with a Remainder exceeding Unity. Therefore its Denominator is Unity with a Fraction whose Numerator exceeds Unity. Thus 9 is said to be in a *Superpartient Reason* to 7, because 9 exceeds 7 by two 7th Parts. This Reason has also infinite *Species* from the infinite Variety of Denominators, which *Species* are so expressed in Words that both the Numerator and Denominator of the Fraction adjoined to Unity, are pronounced in the *Denominator* of the proposed Reason ; as *Superbipartient Tertias*, *Quintas*, *Septimas*, &c. *Ex. gr.* The Reason of 12 to 7 is said to be *Superquinqupartient Septimas* ; in which Expression the numeral *Septimas* distinctly shews by what sort of Aliquot Parts the Antecedent exceeds the Consequent, and *quinqui* (for the Adverb *quinqui*) denotes by how many of the said Parts it exceeds it. And the same Way in others. But (as we have said) an Exception ought to be observed, that the Excess of the Antecedent above the Consequent ought always to be more than one
Ali-

Aliquot Part, or that the Fraction annexed to Unity in its least Terms must not have Unity for a Numerator ; for then the *Reason* will not be *Superpartient*, but *Superparticular* : As *ex. gr.* the *Reason* of 12 to 9, according to this Division will not be said to be *Superpartient*, but *Superparticular Sesquiterce*, because 12 exceeds 9 by one third Part. *i. e.* by 3. Though according to the Truth of the Matter, such Limitation being set aside, this *Reason* may be called *Supertripartient nonas*, as 12 exceeds 9 by 3, *i. e.* by $\frac{3}{9}$ or three ninths of 9, which Fraction is equal to $\frac{1}{3}$. But the Difference of these Reasons requires the Denominators distinguishing them to be expressed in the most simple and the smallest Terms, or otherwise a *Multiple Reason* will in some Measure coincide with a *Superpartient one* ; for instance, the *Reason* of 9 to 3 may be truly called *supersextipartient tertias*, because 9 exceeds 3 by six thirds of three, *i. e.* by six Units ; but it is plain that this *Reason* is expressed much more simply and fitly by saying that 9 is a *Multiple, viz.* the *Triple* of 3. And hence as in the foregoing, the Opposite of this Reason, together with its Species, is easily understood. For they differ only as to the Thing by a Transposition of the Terms ; and as to the Name by prefixing the Particle *sub* : as, *Subsuperpartient, Subsuperbipartient tertias, quartas, decimas, &c.* therefore we will dwell no longer upon them. And these three are the Species of *simple Reasons*, when the Antecedent contains the Consequent only once. There remain other two Species resulting from the first conjoin'd with the second and third, *viz.* *Multiple-superparticular*, and *Multiple-superpartient*, with their Opposites.

Fourthly, when the Antecedent includes the Consequent more Times than one, and one Aliquot Part of it besides, (as 9 contains 4 twice, and a 4th Part of it more) the *Reason* of these Terms in general is said

said to be *Multiple superparticular*; in particular (as in the Example proposed) *double sesquiquart*, and so of others. The Inverse Reason of which, suppose of 4 to 9 is in general said to be *submultiple superparticular*, in particular *subduple sesquiquart*. But

Fifthly, when the Antecedent contains the Consequent more Times than once, and more Aliquot Parts of it, besides than one (as the Number 8 contains the Number 3 twice with two third Parts of it), the Reason of those Terms to one another in general is said to be *Multiple-superpartient*; in particular (as in the Example proposed) *Double superbipartient tertias*; and after the same Manner in others. Also the Inverse Reason of this, as the Number 3 to 8, is in general said to be *submultiple superpartient*, in particular *subduple superbipartient tertias*. I imagine there will be no need of insisting longer upon these Things which are sufficiently manifest.

And thus we have briefly reckon'd up and expounded the Kinds of *Effable Reasons* to be five of *Majority*, with the same Number of *Minority* opposite to them; nor is there any other Reason of *Inequality* expressible in Numbers, which may not be reduced to some of these; as every greater Quantity contains a lesser either (*first*) some Number of Times perfectly, and consequently is a Multiple of it, and this a *submultiple* of that; or (*secondly*) once with one only Aliquot Part of it, and consequently is a *superparticular* of it, and this a *subsuperparticular* of that; or (*thirdly*) once with more Aliquot Parts of it than one, from whence it is a *superpartient* of it, and this a *subsuperpartient* of that; or (*fourthly*) more than once, with one Part of it only, whence it is called a *Multiple superparticular*, and this a *submultiple superparticular* of that; or (*lastly*) more than once with more Aliquot Parts of it than one, therefore called a *Multiple superpartient*, and this on the contrary a *submultiple-superpartient* of that; nor does
the

the Nature of the Thing admit more Ways of containing. Consequently this Enumeration is perfect.

Notwithstanding in *Theon Smyrnæus* (a) I find yet another Species of Reason, by him said to be simply Effable, and its Terms to be as one Number to another, but distinct from the foregoing; which he therefore designs by the Name of *Neuter*, and, says he, *is the Reason of a Number to a Number*, when the Greater is to the Lesser in none of the aforesaid *Reasons*. For an Instance of which he brings the *Reason* which is between the Terms of the Musical Interval called a *Limma* the greater being to the lesser as 256 to 253. And *Meibomius* follows him in the *Dialogue concerning Proportions* for which he is reproached, as if he dreamed: And indeed not undeservedly. Yet *Meibomius*, we see, did not fancy this out of his own Brain, but is supported by the Authority of *Theon*. What then, Is *Theon* in the Wrong? So it seems, since the Reason of a *Limma* is entirely *superpartient*, viz. *superdecupartient ducentefimas quadragesimas tertias*, and therefore not distinct from the foregoing. I can't otherwise untie this Knot, nor excuse *Theon* of Error, but by saying that *Theon*, and perhaps other ancient Mathematicians, understood a *superpartient Reason* for such a *Reason* only, whose Antecedent so exceeds the Consequent that the Residue may be divided into two simple Aliquot Parts of the Consequent (I call those simple whose Numerator is Unity;) As in the Comparison of 11 with 6, the Residue 5 contains 3 and 2, of which 3 is one half, and two one third of the Consequent 6. From whence this Reason is *superpartient* even according to *Theon*, and the Interpretation he gives of a *superpartient Reason*. But according to this Ac-

(a) Cap. 22. 28.

ception, the *Reason* of a *Limma* will not be superpartient: for 13 the Excess of the Number 256 above 243, cannot be divided into two simple Aliquot Parts of the Consequent 243, as will be found by Tryal. *Bullialdus* (a) gives another Example of the Number 29 to 23, either not at all considering, or purposely dissembling this Difficulty, and subscribing to the Error of *Theon*, if it be an Error. For the *Reason* of the Number 29 to 23 is plainly *supersextipartient* 23^{as}, taking a *superpartient Reason*, as it commonly is. But of this enough.

I might have added Rules for investigating any Terms of all these Reasons already expounded; but besides this would be difficult to accommodate to the Understanding of Hearers, and not very profitable, and requiring many Words, would take up much Time; *Clavius* in his *Precedaneous Works* to the *fifth Element* is ready for any who has a Mind; or among the more ancient *Nichomachus* in his *Arithmetical Works*. Here I rest for the present.

L E C T U R E XX.

That Reasons are not Quantities.

WE have explained the Nature, and reckon'd up the *Species* of *Reason* in our last; I come next to discuss some of its *Accidents*. It happens to *Reasons*, according to the common Way of Speech, as to Quantities, to be *added* or *subtracted*, *increased* or *diminished*, *protracted* and *contracted*, *multiplied* and *divided*, and *compared together accord-*

(a) Ad. Cap. 22. The. Smyr.

ing to Equality and Inequality; which last, since it is the principal Thing in itself, and altogether necessary for understanding the rest, as well as for illustrating the whole Doctrine of *Reasons*, we will discourse of it in the first Place. Yet so that it concerns me to speak something by way of Preface, before I enter upon a Thing so subtle and intricate, which, either by the Nature of the Thing, or thro' the Fault of those that treat of it, is involved in a most thick Mist; to clear up which I can neither hope nor promise from my poor Ability: especially since I find it a very difficult Thing to express the Thoughts which occur to me about it in suitable Words, and digest them in a clear Method. *M. Meibomius* declares that he spent five full Years in this Speculation, nor does all that vast Labour seem to produce any Thing sound or solid, beside some little Criticisms. And that great Man *Gregory Vincentius* who is behind none of the modern Geometricians dwelt longer, and took more Pains upon the same, and yet in my Opinion left the Thing as obscure as he found it. What then can be expected from the Study of a few Hours, what (to say no more) from this almost extemporary Writing, about such a perplexed Subject? Nevertheless we must pursue our Method, we must proceed in the Journey we have begun, however rugged and impervious, and suggest something, tho' rough and unelegant to be polished and improved by your more mature Judgment.

These Things being premised, I betake my self to the Business in Hand. But first of all a Question is to be decided conducing very much to the Understanding what is said: *viz.* since Reasons, no otherwise than all absolute Quantities are said to be compared together, according to Equality, or Inequality, compounded or resolved, added or subtracted, multiplied, or divided; it may be doubted in what Sense

these Things are to be understood, whether properly or improperly ; or whether Reasons accurately speaking are *Quantums* properly subject to those Affections of Quantity, *viz. Equality, Inequality, Reason, Composition, Division,* and the rest. Most of the Moderns are of this Opinion, and expressly affirm, that Reason is a *peculiar Kind of Quantity*, and has the Attributes of Quantity rightly applied to it. This *Vincentius* lays as a Foundation to the whole Doctrine of his *Proportionalities* ; and his associate the learned *Tacquet* agrees with him : This Mr. *Hobbs* inculcates without Opposition from his learned Adversary ; and the famous *Borellus* owns the same, *We are now treating*, says (d) he, *of a new Species of Quantity.* Why shall I mention, *Mersennus, Meibomius,* and others, since all with one Consent, especially they who study to innovate about the Doctrine of *Proportionality*, seem to agree in this Opinion ? Nevertheless I must presume to oppose the illustrious Authority of so many great Men. Truth requires most of all to be defended against such powerful Enemies. This Opinion to me seems not only false, but also very prejudicial, because it begets and maintains useless Controversies, and introduces very many Confusions and Errors into the Doctrine of *Proportions*. Some few more Janglings will be silenced, some Difficulties taken away, Errors avoided, and Clouds dispersed, by maintaining that *Reason* is not a Genus or Kind of Quantity, nor any thing subject to Quantity, or any where properly attributed to Quantity directly by itself, but agrees no otherwise with it, than by a *Catachresis* or *Metonymy*. And indeed it seems strange for any one to have thought otherwise ; for since Reason is, and is acknowledged to be a pure perfect Relation, how can it

(d) Ad. 7. def. lib. 3.

pass into another Category, and constitute a Genus of Quantity? Since it is nothing but a Respect of two *Quantums* founded in Quantity, how can it be conceived a *Quantum* of itself, or a Subject of Quantity? Since it is abstractly a Relation how can it be concretely a Thing related? Is not this to confound Things absolute with Things respective, and concrete Names with absolute? Logicians have hitherto taught that *Relations are inherent to, are attributed, and depend upon absolute Things*; but absolute Things, I believe, are never said nor heard by any to inhere to Relations. So neither does it seem plausible to be said, nor possible to be conceived, that Relations respect themselves, that Habitues have themselves this or that Way, that Distances are distant, Similitudes similar, or Comparisons compared. When *ex. gr.* it is said this Reason is greater than that, first (according to the Opinion of our Adversaries, taking that Expression properly,) some Magnitude, or Quantity inherent to the Reason is attributed to it, because of which Magnitude the Reason is referred to another, or in which is founded its Reason to another; then it is said interpretatively and consequently, *this Inequality* is unequal to *that Inequality*, this *Majority* greater than *Majority*: thus absolute Things will be inherent to Relations, and Relations attributed to Relations; concrete Words predicated of their paronymous Terms, and paronymous Terms of abstract Words. Moreover by what Cause and Right a Man in comparing Reasons together, will pronounce them to be properly equal, or unequal, and to obtain a Reason to one another, by the same Cause and equal Right, in comparing the Reasons of those Reasons, he may assign *Equality* and *Inequality* to them, and consequently a new Genus or Kind of Reason: Nay more, he may yet frame other Rea-

sons of these Reasons, and so continually proceed *ad infinitum*. If Reason be a Kind of Quantity distinct from the Quantity of the Magnitudes compared, and if it obtain Reason itself, then this new Reason will by equal Right be a new Kind of Quantity, and the Reason of this Reason will make another distinct Kind, and so we shall have infinite Kinds of Quantity, hitherto never dreamt, nor thought of. But such a liberal and easy Multiplication of Beings, which is neither necessary nor imaginable, is deservedly rejected by Philosophers. I add, that no Quantity of any Reason can immediately be discerned or estimated of itself, it occurs not to the Sense, it shews not itself by its Effects, is not gathered or proved by any certain Reason, as we shall hereafter endeavour to shew. Therefore it is supposed, and affirmed *gratis*, and may with the same Ease be rejected and denied.

But I foresee it may be thus objected against our first Argument: The Relation of a Father to a Son, is it not truly said to be like to that of a Prince to a Subject, of a General to a private Soldier, or of a Pastor to his Flock? And so a Relation is attributed and inherent to a Relation, *viz. Similitude, or Likeness to Paternity*. I answer briefly, first that such Relations as *Paternity* and *Likeness* are of a very different Nature, nor when it is said *Paternity is like*, is such an inconsistent Reduplication and Confusion of concrete Names with abstract committed, as is incurred by saying *a Likeness is like, or Inequality unequal*. But I answer more fully *secondly*, when it is said *Paternity is like the Principate* (or the Relation of a Prince to his People,) *Likeness* is not founded in the Relations themselves, nor in any Thing inherent to them, but in the absolute Things to which these Relations belong; or in other absolute Things, which follow from these Foundations: be-
cause

cause *ex. gr.* to beget a Son and gather together a People, to govern a Family and preside over a City, are like; since to be beloved, to advise, to punish, to help, to provide, to defend, to require due Reverence, Obedience and Gratitude are common to both a Father and a Prince: hence a *Father* and a *Prince* may absolutely be said to be *like*, for many Causes and Reasons, as being affected with *like Qualities* and doing or suffering *like Things*. From whence by a Translation of the Name, the Relations themselves of *Paternity*, and the *Principate* are said to be *like*, not because these Relations in Strictness of Speech are related to one another; (For since a *Relation* is defined to have its whole Essence in Respect to (or from the Consideration of) some Kind or Kinds of Being as distinct from all others, how can it be conceived that Relations which belong to two different Kinds or Species of Being (as that of *Paternity* and the *Principate*) should also be Relations to one another; which would be all one as to say, that that which has its whole Essence with Respect to certain Beings, as they are distinct from all others, has also its whole Essence with Respect to something else which in like manner has its whole Essence from other different Beings as they are distinct from all others? The Inconsistence of which, who does not see?) but because such Qualities or Actions are always conjoined with those Relations, by Reason of which the Terms related are truly accounted to be *like*. Therefore this Relation of *Likeness* is not so much inherent to the said Relations, as concomitant to them, and only therefore attributed to them. And something like this happens in the Subject we are prosecuting. Whatsoever *Equality*, or *Inequality*, or particular Reason does really agree with absolute Quantums, is ascribed to their Reasons. *Ex. gr.* when a *sex-*

tuple Reason is said to be greater than (*viz.* *double* to) a *triple Reason*, nothing is meant but that the Thing denominated by the Number *six* is greater in a *double Reason* than the Thing denominated by the Number *Three*; or that the Antecedent of one Reason is *double* the Antecedent of the other; by Reason of which *Manner of Inequality*, one Reason may *metonymically* be said to be *unequal* to another. For any one will readily own, if he attentively consider the Matter, that a *sextuple Thing* may most truly and properly be said to be the *double* of a *triple Thing* (by applying concrete Words, and consequently involving certain absolute Things;) but it can never be truly and properly said that *Sextuplicity* (using abstract Names) is the double of *Triplicity*. Certainly a *Sextuple* may at any Time be divided into two *Triples*, and a *Triple* may be so doubled, and taken twice, as to compose a *Sextuple*. But *Sextuplicity* itself seems to be something indivisible, nor can *Triplicity* aptly go to a Composition. Indeed $3+3$ equals 6, but I cannot conceive what Sum can be made by *Triplicity* + *Triplicity*. Three Hours is the *Triple* of an Hour, and three Years the *Triple* of an Year, yet I understand not what Sum, mathematically computable, can be made by adjoining that *Triplicity* to this; but rather see that no *Sextuplicity* can emerge from those two *Triplicities*, which are *metaphysically* two. But that these Things may appear plainer, and because no Necessity requires any distinct Quantity to be assigned to Reasons, we shall more closely advert to some Things about the Comparisons of Reasons.

First, I observe, that no Reasons can be so compared together as to make any such Reason, as our Adversaries pretend, known or estimable, except they be first reduced to a *Common Consequent*, *viz.* *immediately, or mediately, actually and explicitly, or virtually*

virtually and *implicitly*. *Ex. gr.* No Body can know, or conceive which Reason whether of the Number 12 to 8 or of the Number 4 to 2 is greater, or which Way greater, but by considering that 12 is to 3 as 4 to 1, and 4 is to 2 as 2 to 1: Or substituting any other common Consequent, suppose 5, in the Room of Unity, by considering that $12. 3 :: 20 : 5$, and $4. 2 :: 10. 5$. This being considered and understood the Inequality, and Reason as it is called, of the *Reasons* proposed is known from the Comparison of the Antecedents in those new *equipollent Reasons*. Therefore it appears also from hence, that *Reasons have no Quantity of themselves* at all imaginable or distinct from the Quantity of their Terms; but yet after they obtain a common Consequent, they are denominated *Inequal* because of the *Inequality* of the Antecedents.

In like Manner it may be adverted *secondly*, that when the Terms of any two Reasons are heterogeneous, they cannot at all be compared or estimated, except they be first reduced to some common Genus. *Ex. gr.* let two Weights, and two Times be proposed, it may hence, and scarce otherwise, be in some Measure known, which is greater, the Reason of these two Weights or Times, by this means. Let a Quantum of any Kind be assumed at Pleasure, but generally a Right Line may be assumed most conveniently (because of the Simplicity of Right Lines above any Thing else, and their Capacity for expressing any Reason,) let any Right Line, I say, be so assumed, if it can be done, that the first be to the second, as some Line to the Line assumed; also that the first Time be to the second, as some Line again to the same assumed Line; then as the former Line thus found is to the latter, so will the Reason of the Weights be said to be to the Reason of the Times; I say,

it will be said to be so because the said Lines are thus to one another, borrowing their Denomination from their Reason. Instead of a Line, a Number may be most conveniently assumed, if the Reasons proposed be explicable in Numbers; but if they be not, which for the most Part happens, then is Number unfit for this Comparison. Whence, I observe by the Way, that a certain great Man in his (a) Arithmetical Works seems not rightly to say *that all Reasons exist in the Genus of Number*: as if other Quantities could not obtain Reason, and that sufficiently knowable, without any Consideration at all of Numbers. But what Way can this Sort of Reason be in the Genus of Number, which can be expressed in other Terms, and yet not in Numbers? In like manner, what he infers hence seems foreign to the Truth, *viz. that the whole Doctrine of Reasons suits more with the Speculation of Arithmetic than Geometry*; for how so, are there yet many Inventions and Doctrines concerning Reasons entirely general, and agreeing alike to all Quantities? Such Reasons also as cannot be expressed in Numbers surpass the Limits of Arithmetic, of which there are innumerable, to which the Theorems of the fifth Element are adapted, as well as to *Arithmetical Reasons*. But this by the Way: I do not know that it can be better explained otherwise. Consequently it may be moreover observed,

Thirdly, that no Reason can be estimated or comprehended separately, and by itself, nor is peculiarly capable of being expressed or represented by any determinate Quantity, but by all or any one indifferently; nor consequently is it subject to any absolute Quantity; for what Sort of Quantity can that be, which passes through all the Genera of

(a) Wallis Arith. p. 226.

Quantums? And if it have no intelligible Quantity of itself, how can it be conceived to have any, when compared with another Reason? How can a Comparison of Quantities comprehensible of themselves be made without any Reason, or how can there be a known Relation of unknown Quantities? Moreover a Reason compared with another Reason obtains only a loose and arbitrary Quantity; for as the common Consequent is taken differently at Pleasure, so what are called the Quantities of the Reasons compared are different. Therefore these Reasons have but a desultory and indeterminate Quantity, *i. e.* none. For whatsoever is, is something determinately; and that which is not so, is nothing. The most sagacious *Vincencius* saw this, and plainly owned and declared as much; but whether being deluded by the Ambiguity of the Words, or something elated with the Hope of being the Author of a new Science, he gives it another Turn. *I answer;* says he, *it is true, if the Reason, which cannot be expressed in Numbers, be taken solitarily, that its Denominator cannot be represented Geometrically.* But I here interpose that it may always be exhibited, by taking any Quantum for the Consequent; which will perform the same Office that Unity commonly does in representing or exhibiting the *Denominators of Effable Reasons*; nor is there any thing peculiar in this Respect to Reasons effable in Numbers. But *Vincencius* proceeds, *But if there be two or more given Reasons, the Denominators of each may be assigned, which may demonstrate what Proportion is between the Reasons themselves; and this will not only be performed by two certain Lines, but by any others, that are proportional to the former.* Thus he. Since therefore there can be no Quantities of Reasons assigned, beside such Denominators; but if taken simply there can, though various; it follows,

there will not be any Quantity of Reasons absolutely determinate: But *Vincentius* (as I said) seeming to be deceived with the Obscurity of certain Words, has turned these Things beside the Purpose.

Wherefore I observe *fourthly*, that the only Foundation, upon which the Doctrine, we are opposing concerning the *Quantities* and *Reasons of Reasons*, depends and seems to be deduced, is the customary Manner of speaking: *These two Magnitudes are equally unequal with those two; these are more or less unequal than those*; from whence they infer there are *Quantities* and *Reasons of Reasons*. If this Reason be greater than that, then they are *Quantums*, and this has a Reason to that. *From whence* (says Mr. *Hobbs*) *it is understood that the Reason both of Excess and Defect are Quantities* (or *Quantums*) *as receiving* (i. e. as capable of being said to be) *greater and lesser*. And *Vincentius* in the first Demonstration of his Book concerning *Geometrical Proportionalities*, argues thus: *Reason is a certain mutual Habitude of an Antecedent to its Consequent, according to Excess and Defect, and Equality. When therefore the Antecedent of one Reason exceeds, or falls short of its Consequent, more than the Antecedent of another Reason exceeds or falls short of its Consequent; it is manifest that one Reason is greater or lesser than the other, as much as one Quantity is greater or lesser than the other.* But to this plausible Discourse I answer. In the usual Forms of Speech we are not to regard the Sound of the Words, but the Meaning of the Speakers. And it was just now sufficiently shewn that nothing can be conceived by this Sort of Words, but that when the Reasons of any *Quantums* are reduced to a common Consequent, their Antecedents exceed, fall short of, or are equal to one another. For, as themselves are forced to confess, no Rea-
sons

sons can be estimated or compared together, till such a Reduction be made; and after they are so reduced, this, which they call a *Reason*, is only known and denominated from the Comparison of the Antecedents. And these Antecedents are by themselves called the Denominators of the Reasons. Therefore nothing else is necessary to be designed or understood by the aforesaid Expressions, but the *Equality* or *Inequality* (*i. e.* the *Reason*) of the *Antecedents*. Nor therefore is the Argumentation deduced from these Forms of Speech of any Force. I said nothing else is necessary, but in Fact nothing else is conceivable; whence to put an End to this Dissertation,

I observe *fifthly*, whatsoever is vulgarly attributed to Reasons, that only truly and properly agrees with the Denominators of Reasons, *i. e.* with the Antecedents of Reasons reduced to the same Consequent. The Quantity, they assign to those, is nothing else but the Quantity and Reason of the Denominators; and when they would be thought to add or subtract the Reasons themselves, they only add or subtract these Denominators; also when they multiply or compose, divide or resolve them, it is the same. This will appear to any who attentively examines the Propositions of *Vincentius*, which are indeed composed with exquisite Labour, and are proposed universally, and lawfully demonstrated according to his Definitions and Hypotheses; but if any one take them particularly, as meant concerning Numerical Reasons, he will find his whole Doctrine to terminate in this, That the Addition and Subtraction, Multiplication and Division, and Comparison of Fractions as to Proportion, are delivered as numerical, or as they are Quotients found by Division. And what a numerical Fraction, or Quotient of Division is in Arithmetic, the same is the Denominator of any Reason

Reason in Geometry ; *i. e.* any Magnitude, so affected, is referred to the homogeneous Magnitude put in the Place of Unity, as a numerical Fraction or Quotient to Unity. Wherefore *Vincentius* seems to prosecute nothing else but Arithmetical Fractions, and the Denominators of Geometrical Reasons answering them ; to which he ascribes all the Properties agreeing with Reasons themselves. *Ex. gr.* Suppose the two *Numerical Reasons* of 3 to 5 and of 7 to 3, the Denominators of these Reasons will be the Fractions $\frac{3}{5}$ and $\frac{7}{3}$ (since $\frac{3}{5}$ to 1 is as 3 to 5 ; and $\frac{7}{3}$ to 1 as 7 to 3 ;) or by reducing the said Fractions to a *Common Denominator*, the Denominators of these Reasons will be the fracted Numbers $\frac{9}{15}$ and $\frac{35}{15}$. Therefore when he added these Fractions to, or subducted them from, one another, when he multiplied or divided the one by the other, and when he exhibited their Proportion ; he pretended to have added or subtracted, multiplied or divided the said Reasons themselves, or to have exhibited their Reason. That great Man therefore, as *Tacquet* thinks, did not frame any new Science about Proportions, but only fashioned the old Doctrine in another Model, and that not over apposite, and delivered it in new Words ; which yet he has enriched with many Theorems invented by himself. And as we have said, it is common to him with the rest, that embrace this Doctrine (*viz.* concerning the Reasons and Quantities of Reasons,) to confound Reasons with numerical Fractions, while they are meddling with Numbers ; and to handle the same by their Denominators, while they are considering other Reasons. Which they sometimes do openly, and in express Terms, but oftner otherwise. Mr. *Hobbs* does often take notice of this, and reprove it in his Antagonist, but it appears that he himself is not altogether free of the same Fault ; for it is the same Thing to attribute Reason

to Reasons, as to account Reasons the same with their Denominators, or at least to speak nothing and insignificantly ; for they mean this or nothing. But this may suffice in some measure for explaining and confirming our Opinion, that Reasons have no Quantity properly so called, nor are they truly compared together, as to Reason. From whence we will deduce some Confectaries. As

First, hence will be easily decided the Question which *Euclid* terms concerning the Composition of Reasons, whether it is more rightly accounted the Addition or the Multiplication of Reasons : for from what has been said, with Respect to the Thing itself, Reasons, as void of Quantity, can neither be added nor multiplied ; but as to the Manner of Speech, because when Reasons are said to be compounded their Denominators are multiplied, it is manifest that Reasons are more rightly said to be multiplied than added. As also, when one of the Denominators divides the other, the Operation will be more justly called a *Division* than a *Subtraction* of Reasons. Though it has obtained, to have the former Operation called *Addition*, and the latter *Subtraction*.

Secondly, Hence is entirely overthrown, or fully decided the Controversy, which some do agitate, and which seems to have been raised by (a) *Mersennus*, viz. Whether a Reason of Equality refers, or is equal to nothing, a Reason of greater Inequality is above nothing, and a Reason of lesser Inequality below nothing. For in Truth since no Reason is a Quantity, the fundamental Hypothesis of this Question falls to the Ground, and the Question itself along with it. But from the Hypothesis, that the Affections of the Denominators are to be applied to their Reasons, it also appears most evi-

(a) In *Præfat. ad Cogit. Physico-Mat.*

dently,

dently, that the Reasons of *Minority* and *Equality* arise above nothing. For the Denominator of a lesser Reason is always some Quantity less than the Consequent; and consequently in Arithmetic is a Part or Fraction less than Unity. And the Antecedent of an equal Reason being always adequate to the Consequent, its Denominator in Arithmetic is denoted by Unity. Nor is any Thing farther required for the Decision of this Question.

Thirdly, Hence is easily refuted all that *Meibomius* advances against the ancient as well as modern Geometricians, in a Stile but too indecent and unmannerly. As when he affirms, that a *submultiple Reason* is the same with a *multiple Reason*, because of the same *Distance from Equality*. For besides that the Distance is not the same (for how far is a Defect from an Excess, or a negative from a positive Distance,) it will sufficiently appear by reducing those Reasons to a *common Consequent* (which we have so often shewn to be necessary for the Comparison of Reasons,) that the Denominator of a subduple Reason will be lesser than a Denominator of a double Reason, by a quadruple Reason: For if the common Consequent be 2, then will the Antecedents be 1 and 4. And when he concludes that Reasons of Excess and Defect cannot be compared together, he is evidently mistaken, for these as well as any other, may be compared by Help of the Denominators. Also, when he says, that a lesser Reason only can be taken from a greater (he would have said more rightly a lesser divided by a greater, as was premonished,) he is plainly in the Wrong: for what hinders the Denominator of a lesser Reason to be divided by the Denominator of a greater, either *Arithmetically* or *Geometrically*? Again he mistakes, when he pronounces the Reason of Something to a greater to be often greater than the Reason of the same

same to a lesser; as that the Reason of 4 to 7 is greater than the Reason of 4 to 5; and consequently that the Names of *Greater* and *Lesser Reason* are hitherto used amiss by all Geometricians. For if we reduce these Reasons of 4 to 7 and 4 to 5 to the same Consequent, by substituting *ex. gr.* the Equipollent Reasons of 20 to 35 and 28 to 35, it is apparent that 20 is less than 28, and consequently the Reason of 4 to 7 less than the Reason of 4 to 5. And hence it appears universally that the Appellations of *Greater* and *Lesser Reasons* are most fitly applied by the Ancients; *viz.* because they are lawfully derived from the Quantities of the Antecedents after Reduction, as the Reason of the Thing requires; from whence both the Reasons themselves are discovered, and receive their Denomination, and are at all capable of being any way compared or comprehended. Wherefore it is also abundantly clear, that the same Person has no solid Reason for opposing the Definitions of *Euclid* as false. For if any Reason be greater than another, which himself does not deny (and if none be properly greater, which I think to be the Truth but for Argument sake will not insist upon it;) I say, if any Reason be supposed greater than another, that surely will be most worthily called *Greater*, whose Demoninator is greater, and which is named such by *Euclid*, and is notoriously circumscribed in the Definition, and distinguished from others. With the same Ease are all the Paradoxes dispatched, which that Person has suggested contrary to the common Sentiments of Geometricians.

Nor *lastly*, will that *Logomachy* that is so tossed about be very troublesome to us, about *Multiple* and *Multiplicate*, *Double* and *Duplicate*, *Triple* and *Triplicate*, and the like *Reasons*. For from what has been delivered, it manifestly appears that *ex.*

gr. what is called *Duplicate Reason* is not the Double of the Reason with which it is compared: As the Reason of the Number 9 to 1 is not double the Reason of 3 to 1, because the common Consequent of these Reasons existing, the Denominator of the one 9 is not equal to double the Denominator of the other 3. From whence it appears that the Multiplication of such Reasons are named from another Cause, hereafter more conveniently to be shewn.

I will only add this, that if it be admitted, which I have been endeavouring to prove, *that Reasons have no Quantity of themselves, nor any Attributes of Quantity*, but as they are referred to their Denominators; hence very many of this Kind of Difficulties will immediately vanish, many Doubts be entirely taken away, or easily solved, and many Contentions and Strifes laid asleep, which seem more to have proceeded from the Ambiguity introduced by this false Hypothesis, than from any Thing else. Wherefore I thought it not foreign to the Purpose to handle this Question so largely and fully.

But because Reasons commonly use to be compared together, and called *equal, greater, or lesser*; nor does it seem that a Licence was ever denied the Teachers of Sciences for inventing and using such Words for Clearness and Brevity's sake, so they be proper, and give no Occasion of Error. For I am not willingly disproving the Vulgar Ways of Speech, but am investigating their genuine Sense, that Words may not hurt Things, and the Truth not be imposed upon by empty Sounds. Therefore we will enquire in the next Lecture what is distinctly signified by the Ways of Speech heretofore admitted, and long in Use not without some Foundation, and probable Cause, *viz.* we will seek what *Reasons* are *Equal, Greater, or Lesser*.

Lesser by expressing these Comparisons of Reasons in another manner briefly and not unelegantly ; what is *Analogy*, what *Hyperlogy* or *Prology*, what *Hypology*, and how they may be rightly refined and distinguished from one another : Than which perhaps no Controversy disputed among Mathematicians is more subtle or of greater Consequence. In my Opinion these Definitions are best performed by *Euclid* (as far as the Thing itself will suffer) but to very many it now seems otherwise, and he is condemned and forsaken by almost all in this : Whether they do this for just Causes, and depending upon valid Arguments, it will be in your Judgment to determine from an Examination of what I shall say. In the mean Time, farewell.

LECTURE XXI.

A Defence of Euclid's Definition of Proportionals in his fifth Book.

IT seems to be sufficiently proved in the preceding Lecture, that *Reasons* truly and properly speaking do of themselves admit no Quantity, no Reason, nor therefore can one be predicated *greater*, *lesser*, or *equal* with Respect to another, because of any Thing inherent in, or agreeing with themselves ; but these Attributes are derived from the absolute Quantums upon their Reasons. But because Custom has so long prevailed to have Reasons compared together like absolute Quantums, and the Names of an *Equal*, a *Greater*, or a *Lesser Reason* has obtained, and we do not unwillingly admit these Expressions with due Caution ;
it

it next follows that we enquire by what certain Sign or Mark it may be known, when a Reason may be said to be *equal* to another, when *greater*, when *lesser*, *i. e.* how a Reason can be defined and distinguished *greater*, *lesser*, or *equal*. And indeed it seems plainly enough to follow from what has been said, that, if two Reasons consisting of homogeneous Terms have a common Consequent, they may be most appositely defined by the respective Quantities of their Antecedents, *viz.* so that those are to be called *Equal Reasons* whose Antecedents are Equal, this *greater* than that, when the Antecedent of this is greater than the Antecedent of that, and this *lesser* than that, when the Antecedent of this is lesser than the Antecedent of that. But since it often falls out that Reasons of a different Consequent are compared, and consequently this Condition fails, therefore some other *universal Sign* is required to discover the Relation of those Reasons, which may be sufficient for determining the Habitues of all Reasons to one another. And we have hitherto found it a Thing of great Difficulty to find such a sufficient *Sign*; since various Causes hinder, especially two, *viz.* the *Difference* between *Effable* and *Ineffable Reasons* (*i. e.* the *Incommensurability* of Quantities) and the *Heterogeneity* of the *Terms* of which different Reasons consist. For if all Reasons were *Effable*, and only between commensurable Quantities, an *Equal Reason* might be the same Way defined with the *Proportionality of Numbers* in the *fifth Element*, *viz.* by the equal Quotients of the Divisions, and a *Greater* and a *Lesser Reason* by the Inequality of the Quotients respectively: but the *Incommensurability* of the *Terms* of most *Reasons* hinders this from being universal, by which it happens that the Division cannot be performed exactly, nor expressed in common Numbers, nor the *Manner* whereby the

Terms

Terms respect one another clearly conceiv'd. Also the *Heterogeneity* of the Terms of the Reasons compared exclude some other Ways deviseable, whereby the Respect of the Reasons might be otherwise defined, which perhaps shall be hereafter shewn. Hence it seems very difficult to exhibit any *Universal Mark*, by which it may plainly and certainly be pronounced concerning the *Equality* or *Inequality* of any two *Reasons* propos'd, whose *Terms* are indifferently *commensurable* or *incommensurable*, *homogeneous* or *heterogeneous*.

Let us see then what sort of *Marks* Geometricians endeavour to assign; or by what Means they attempt to define these Respects of Reasons. And because, if a good Definition of an *Equal Reason* could be conceived, it would not be difficult from thence to form Definitions of *Unequal Reasons*, *greater* as well as *lesser*, therefore we will first treat of the *Equality* of *Reasons*, which is accounted the very Soul and Kernel of the whole Mathematicks, ay, as *Plato* says, *the Chain of all Disciplines* (a).

We will begin then to handle a Matter of such Consequence from the very Foundation. An *Equality of Reason* in one Word (for Brevity and Clearness sake) is wont to be called *Analogy*. Which Word, tho' it vulgarly denotes any Agreement, Conformity, or apt Correspondence of certain Things with one another, foreign to the Mathematics; for Instance, the *Agreement of Speech with the general Rule* is by Grammarians called *Analogy*; and the Things that conspire in any common Reason are by Logicians said to be *analagous*. The Proposition *ana* in the Greek signifies any sort of *Identity*, *Equality*, or *Agreement of Things*. Examples are in the holy Scriptures. In the second of *John*, verse the sixth, *Containing two or three Fir-*

(a) In *Timæo*.

kins (*ἀνά*) *equally*. In the twentieth of *Matthew*, verse the tenth, *And they received a Penny (ἀνά) each, or equally*. In the ninth of *Luke*, verse the fourteenth, *Make them to sit down by Fifties in a Company (ἀνά) equally*. And none are ignorant that it is prescribed to the Students of Medicine in the Composition of their Drugs, to take such Measures of such or such Things *ana* i. e. *equally*. The same Way almost are two Pairs of Quantities said to be *Analagous*, when each Pair have their (*Logos*) Reason (*ana*) equal; and abstractly such an Agreement of the same Reasons is called *Analogy*. The same is in Latin more commonly called *Proportionality*, because *Proportion* in that Tongue for the most Part signifies the same with (*Logos*) Reason. Tho' *Cicero* in his Version of *Plato's Timæus* translates the Greek Word *Analogy* by the Latin Word *Proportion*. And *Fabius Quintilianus* (*b*) thought *Analogy* ought to be expressed by *Similitude* or *Likeness*: wherefore *Analogy* or *Proportionality* by *Euclid* is defined a *Similitude of Reasons*; and by *Theon Smyrneus* an *Identity of Reasons*. Tho' in my Opinion it would be better defined (but it is of no great Consequence) an *Equality of Reasons*, both because the Word *Similitude* is too loose and ambiguous, and *Identity* does not so well agree with Things actually different compared immediately as such; and because other Habitues of Reasons, viz. *Hyperlogy* and *Hypology* are not denominated *Majority* and *Minority* from *Dissimilitude* or *Diversity*, but from *Inequality*; and lastly because the *Denominators* of equal Reasons, by which the Reasons are capable of Comparison, are not the *same*, or *similar*, but *equal*. Yet these Definitions don't exhibit any certain essential Affection of the Thing defined, but only shew in Part, what the Word *Analogy* signifies; at least they are such

(b) Quintil. lib. V. H.

in *Euclid*, as appears from hence, because he in his *fifth Element* subjects it to the Definition of Magnitudes having the same Reason; *Magnitudes*, says he, *having the same Reason are called Analogous or Proportional*; which is a meer Explication of the Word *Analogous*. And immediately after the Definitions of Magnitudes having an unequal Reason, *Analogy* (says he) is a *Similitude of Reasons*. Wherefore *Borellus* does not well conceive *Euclid's* Meaning, when he thinks that he proposes this Definition as essential and scientific to *Analogy*, and imagines a *Similitude of Reasons* to be here assign'd, as the known and first Property of *Analogy*. For he seems to have thought no such Thing; but since often the Word *Analogy*, or *to be Analogous*, more elegantly and concisely expresses an *Equality of Reasons*, and sometimes seems to be used, he was willing to explain it, that Learners might not be over much burthen'd with Labour, nor confounded with Obscurity. Wherefore he does not deservedly tax *Euclid* in supposing him to have delivered that Definition, as superfluously and mistakenly, exhibiting two Definitions of the same Thing. For he has really exhibited only one general Definition of Things having *the same or equal Reasons* by one of their essential Affections; but what Cause pray should hinder him from intimating besides that Things having an equal Reason are called *Analogous*, and that the *Identity or Similitude of Reasons* may be also designed by the Name of *Analogy*? He had Cause enough to declare the Force of a Word unknown perhaps to most.

But there seems to have been a Wrong done to *Euclid*, because in *Clavius's*, and most other Latin Editions of the Elements, the Description of *Analogy* is put in the fourth Place, which ought to be in the eighth. Therefore that censorious Person

rightly mistrusts that this Description is wrong placed, and perhaps he had not found so much Fault with it, if it had been otherwise. Albeit I don't deny, but to any one, who more attentively examines the Definitions of the *fifth Element*, something seems misplaced in the *Greek* thro' the Default of Transcribers ; wherefore it is not now opportune to enlarge upon Conjectures. And the rather because we are engaged to find an apposite and accurate Definition of an *Equality of Reasons*, or *Analogy*, which is the principal Thing in this Subject. Which we will do after this Method. *First*, we shall explain *Euclid's* Definition, and shew how it exactly agrees with all the Conditions of a lawful Definition: *Secondly*, we will observe and remove the Objections brought against this Definition: *Thirdly*, we will examine the new Doctrines and Methods of such as substitute in the Room of this Definition, and assay to shew what is deficient in them, and how far they give Place to, or fall short of, *Euclid's* Definition.

As to the *first Head*, the Definition in the *Elements*, according to *Clavius*, is this: *Magnitudes are said to be in the same Reason, a first to a second, and a third to a fourth, when the Equimultiples of the first and third according to any Multiplication whatsoever are both together either short of, equal to, or exceed the Equimultiples of the second and fourth, if those be taken, which answer one another ; i. e.* if the Multiple of the first Antecedent be compared with the Multiple of its Consequent, and the Multiple of the second Antecedent with the Multiple of its Consequent. Such is *Euclid's* Definition of Proportions ; that *scare-Crow* at which the over modest or slothful Dispositions of Men are generally affrighted : they are modest, who distrust their own Ability, as soon as a Difficulty appears, but they are slothful that will not give some Attention for the learn-

learning of Sciences ; as if while we are involved in Obscurity we could clear our selves without Labour. Both which Sorts of Persons are to be admonished, that the former be not discouraged, nor the latter refuse a little Care and Diligence when a Thing requires some Study.

But this Definition may be conceived in other Words, a little more briefly, and perhaps more suitably to some People's Capacities. *Quantities are Analagous or Proportional Pairs to Pairs, when any Equimultiples of the Antecedents are together always either equal to, or greater, or lesser than any Equimultiples of the Consequents, ordinately. Or thus, Quantities are Analagous, when the Antecedents being any how the same Way multiplied, do perpetually keep the same Kind of Reason to the Consequents being also any how the same way multiplied.* I have said *the same way multiplied*, but by the Way, I might have said *the same way divided* ; *i. e.* for *Equimultiples* I might have taken like *Aliquot Parts* ; that the Definition be render'd agreeable to *Euclid's*. *Quantities are Analagous, when any like aliquot Parts of the Antecedents are always together greater than, or equal to, or lesser than any like aliquot Parts of the Consequents : Or, when the Antecedents, being any how the same way divided do together retain the same Kind of Reason, with the Consequents, being any how the same Way divided.* And those might be so coupled in the same Definition, as to contain disjunctively both *Equimultiples* and like *Parts*. After this manner *Quantities are Analagous or Proportional, when the Antecedents being any how the same Way multiplied or divided have always the same Kind of Reason to the Consequents, being any how, &c.* *Euclid*, I say, might have formed his Definition of *Proportionals* either of these Ways with equal Reason, as to the Thing. But because *Division* seems to be something more intricate than *Multipli-*

cation, and the Calculus of Integers is more simple, and easier to be conceived, than that of Fractions, and more readily dispatched; therefore he seems designedly to have selected and applied *Equimultiples*, rather than *like Parts*. And the Occasion why he thus declares *Proportionality* is, because he investigated the general Definition as well of those equal Reasons which consist of commensurable Terms, as of those, whose Terms are incommensurable, and consequently whose Reasons themselves are not *effable*; also because the Antecedents of *ineffable* Reasons do so respect their Consequents in an explicable Manner, that it can scarce be conceived how they do immediately contain them, or are contain'd in them; therefore some universal Property of both Effable and Ineffable Reasons, connected with Equality, and sufficient for determinating it, ought to be fetched elsewhere, and not from the Way or Manner of containing, by which he might have easily defined the Equality of Effable Reasons, and indeed actually has defined it, in the *seventh Element*; which Property while he diligently sought for, examining all, at length he consider'd, that some Quantities are so combined, or connected together, or do so depend one upon another, as to the manner of their Quantity, either from some special Property of their Nature, or by Reason of some Condition assum'd, that both the Equality or Inequality of these do follow from the Equality or Inequality of those; and also every like Increment or Decrement of these, does carry along with it the like Increment or Decrement of those. *Ex. gr.* any two Triangles of an equal Height by a certain particular Property of their Nature, demonstrated in the first Element, are so connected with their Bases, that if the former be any how encreased or multiplied, its Basis will be also encreased or multiplied in like Manner: and as the latter is encreased or multiplied, so in like man-

ner is its Basis encreased or multiplied: as also if the former Increment or Multiple be greater than the latter, the one Basis answering to it will be greater than the Basis of the other Increment or Multiple; if that be lesser this will be lesser; if that be equal this will be also equal. Again, any two Wholes, with their aliquot Parts, because of that assumed Condition of *Likeness*, are so connected, that all the Multiplications of the one do include and convey along with them, the like Multiplications of the other respectively; and if the Multiple of the former Whole exceed, fall short, or equal the Multiple of the latter; then the Multiple of the Parts of the former will also do the same with the Multiple of the Parts of the latter. This when our Author consider'd, and moreover found it to happen otherwise in Quantities otherwise affected, *ex. gr.* as we shall shew hereafter, in Triangles of a different Height, from the Excess of the one the same Way multiplied with its Basis above the Multiple of the other is never infer'd the Excess of its Basis above the Basis of the other the same Way multiplied with the other: neither if the Wholes be compared with their unlike Parts, from thence because the former equally multiplied with its Parts exceeds some Multiple of the latter, will it any Way follow that therefore the Multiple of the Parts of the former exceeds the Parts of the latter equally multiplied with its Whole? Those Things, I say again, when *Euclid*, or whoever else was the Author of these Definitions, observed and saw the said Property to agree with all Kind of Quantities promiscuously, whether commensurate or incommensurate, tho' no Consideration of any Commensurability or Incommensurability there intervenes; hence he thought that the mutual Respects to one another of the Reasons, happening to Quantities so affected, are to be estimated and defined from it. *Clavius* thinks that our Author,

when he first perceived this Propriety to happen to any commensurate Quantities, at the same Time finding it to agree with any four incommensurate Quantities, from thence by his own Authority reckon'd *Proportionality* in general to be determined from it. But I rather incline to think, when he found that to happen not only to *analogous Terms* of an Effable Reason so denominated according to some former Definition; but also, as I have hinted, to all that are connected together by the special Property of their Nature, or by an assumed Condition, he imagin'd that the Habitues of Reasons of this Sort were to be distinguished by it from others; which he called the *same* or *equal*, because if at any Time it happen'd for such Reasons to have or be capable of being any Way reduced to the same Consequent, their Antecedents were always equal. Albeit perhaps the Author of this Definition reason'd thus with himself; it is seen from a confused Notion of Equality, as that seems to carry with it the highest Similitude of Reasons, that the Antecedents in the same Kind of Reasons are referred together to their Consequents. But if the Antecedents be both multiplied by any one Number, it plainly appears that this *Likeness*, as to the Kind of the Reason, is never changed, since those Terms encrease the same Way. And if the Consequents be also multiplied by any one and the same Number, the same *Likeness* will still remain, and the same Kind of Reason be retain'd on either Hand: tho', as the multiplying Numbers are assumed greater or lesser, are the particular Quantities of the Reasons thus unchangeable, varied, encreased and diminished innumerable Ways; so that often the Antecedent Terms are equal to the Consequents, often short of them, or exceed them more or less. Perhaps that sagacious Man has reached the bottom of this Affair, and from thence drawn us this Definition by this sort of

Dis.

Discursus, which is something Metaphysical, but not very obscure. But by whatsoever Ways or Means the Author came to the Knowledge of this Property, however as its Invention was most subtle, so is its Use excellent and very opportune to the Matter proposed; for from hence he deduces most of the principal general Affections of Proportionals most immediately, directly, briefly, and clearly; and also shews the *Proportionalities* of particular Quantities, which we shall speak of hereafter.

But first of all let us explain the foregoing Definition. The apposite general Condition is chiefly and especially notable, *according to any Multiplication*: for it is not sufficient for the *Equimultiples* of the homologous Terms, thus affected (*viz.* to exceed, fall short of, or be equal together) to happen sometimes, but it must be evinced by manifest Arguments to fall out always. It must, I say, be evinced, not from any perpetual Induction (Induction being a Thing of infinite Labour, and not agreeing with the Mathematics) but must be derived by an universal Demonstration, from some essential Property of Particular Quantities or Use founded in some peculiar Conditions supposed or discover'd of some more universal Quantities. This *simultaneous Defect, Excess, or Equality* may in some Cases happen to Quantities not proportional, but it happens to *Proportionals* alone universally, necessarily flowing from their Constitution, and consequently may and ought to be universally demonstrated of them, that their *Proportionality* and Agreement with this Definition may appear. But this Definition cannot be better illustrated than by Examples, by which Means it will appear most evidently, that this Condition really agrees to most Quantities, and that this Definition may be easily applied, as not being difficult to be understood, and yet apt enough for Use. We will begin with more particular Examples.

Let there be two Triangles (*a*) ZAB and YMN of an equal Height, or between the same Parallels, upon the Bases AB and MN. Here are therefore two Quantities; *viz.* Two Triangles ZAB and YMN and two Bases AB, MN, to which I affirm the Condition of our Definition happens. For let the Antecedent Terms be any Way equally multiplied at Pleasure, *viz.* the Triangle ZAB and its Basis AB. *Ex. gr.* according to the Number *Three*, by assuming the Right Lines BC and CD equal to AB, and drawing the Right Lines ZC and ZD; for it appears from the Equality of the Basis AB, BC, and CD, that the Triangles ZAB, ZBC, and ZCD are also equal. In like manner let the Consequents, *viz.* the Triangle YMN and its Basis MN be multiplied equally at Pleasure, suppose with the Number *Two*, by taking the Right Line NO = MN, and connecting the Right Line YO. Then from what is demonstrated in the first Element, it most plainly appears, if ZAD the *Triple* of the *Antecedent Triangle* exceed YMO, and the *Double* of the *Consequent Triangle*, that AD the *Triple* of the *Antecedent Basis* will also exceed MO the *Double* of the *Consequent Basis*; and if a Defect be there, a Defect will also be here; if an Equality there, an Equality will be found also here. Therefore these four Quantities obtain the Condition required in this Definition, nor is this drawn from any Induction, but from an universal Discursus.

Again let there be a Circle whose Center is Z, (*b*) and two Angles at the Center AZB and MZN standing upon the Arches AB and MN: it may be shewn that the Condition of this Definition also agrees with those Angles and Arches. Let any Multiple of the Arch AB, suppose the *Triple* AD, be assumed, and let ZD be connected. It appears

(*a*) Fig. 6. (*b*) Fig. 7.

from

from the *third Element*, that the Angle AZD is also triple the Angle AZB. Then let any Multiple of the Arch MN be taken, suppose the double MO, and let ZO be connected. In like manner it appears that the Angle MZO is double the Angle MZN. But if the Angle AZD exceed the Angle MZO; from what is demonstrated in the *third Element*, the Arch AD will also exceed the Arch MO; and if that equal that, also this will equal this; but if a Defect be there, also a Defect will be here. Therefore it is shewn that the said Condition agrees with these Quantities by a certain universal Demonstration.

Furthermore, for I shall add several Kinds of Examples for a more perfect Explication of this Subject; Let there be two Spaces ZA and XM (*a*) run thro' with an equal Velocity by a Body moved uniformly in different Times represented by the Line $\zeta\alpha$ and $\xi\mu$. I say the foremention'd Condition will agree with these Spaces and Times; for let any Spaces AB and BC be assumed equal to ZA, and as many Times $\alpha\beta$ and $\beta\gamma$ equal to $\zeta\alpha$. And let the Space XN be equimultiple of XM, and the Time $\xi\nu$ of the Time $\xi\mu$. It is plain that $\zeta\gamma$ is the time of the Passage through ZC, and $\xi\nu$ is the Time of the Passage thro' XN: *viz.* from the Definition of a uniform Motion, according to which the Spaces run through in any equal Times are equal; and contrarily the Times are equal in which equal Spaces are made. Also because of the equal Velocity from the Hypothesis, if the Space ZC be greater than, lesser than, or equal to the Space XN, will the Time $\zeta\nu$ be in the same Order respectively greater, equal or lesser in respect of the Time $\xi\nu$? From whence it is apparent that these four Quantities are to one another according to the Condition laid down in our Definition.

(*a*) Fig. 8.

Again,

Again, if that be assumed, which is agreeable to Reason as well as Experience, that the Moments or motive Powers of Weights are so increased or diminished according to their Distances from the Center of a Balance, that the equal Increments or Decrements of the Distances do superadd to, or deduct from, the same Weights, equal Moments; hence it will be proved according to this Definition, that the Moments of equal Weights are proportional to their Distances: As if the Point Z be the Center (*b*) of a Balance, upon which equal Weights are hung at the Intervals ZA, ZM and the Right Lines $\zeta\alpha$, $\zeta\mu$ do represent their Moments according to the said Distances; any Equimultiples being taken ZC and $\zeta\gamma$ of ZA and $\zeta\alpha$; it appears from the Supposition just now laid down, that $\zeta\gamma$ is the Moment of the Weight hanging at the Distance C. And likewise the Equimultiples ZN and $\zeta\nu$ being taken of ZM and $\zeta\mu$, it appears that $\zeta\nu$ is equal to the Moment of the same Weight hanging at N. But if ZC exceed, equal, or fall short with respect to ZN, also the Moment $\zeta\gamma$ will also correspondently exceed, equal, or fall short with respect to $\zeta\nu$. Therefore the Quantities ZA and ZM are *proportional* to $\zeta\alpha$, $\zeta\mu$, according to *Euclid's* Definition. By like Means may this Condition be adapted to any particular Subjects, as far as, after this Condition is drawn from any Property of the Quantities proposed, their *Proportionality* may be demonstrated by it.

But more Examples may be suggested of universal Quantities, *i. e.* of such as are confined to no Species of Quantity, to which this Definition may be accommodated by reason of some Condition annexed. As if any two equal Quantities be taken A and B, and any other two equal to them C and D; it will be demonstrated that A and B are proportional to C and D. For it may be easily deduced from

(*b*) Fig. 9.

this

this Condition of Equality, either Way supposed, that this Property agrees with them. The whole *fifth Element* almost consists of such Examples; nor is there any other Thing handled there, but to the End that this Property may be shewn to agree with all Quantities endowed with a certain Condition, and from thence that the Name of *Proportionality* is due to them. Wherefore I will dwell no longer in bringing more such Examples, after I have only added one, from whence it appears almost universally, that most Definitions substituted by others, *i. e.* the Properties by which others define the *Analogy* of Quantities may be deduced and demonstrated from this Definition.

Let any two Pairs of Quantities A, B and C, D be *proportional*, according to this Definition, *i. e.* let the Reason of A to B be equal to the Reason of C to D: I say, it follows, that the Quantity A divided by B is equal to the Quantity C divided by D, *i. e.* that Affection agrees with them, from which *Euclid* in the *seventh Element* has defined the *Analogies* of commensurate Quantities, and by which some also think the *Proportionality* of Incommensurate Quantities may not be inconveniently defined. Forasmuch as if A and B *ex. gr.* be supposed incommensurate, then A cannot be so divided by B as to have a rational or effable Quotient, yet some such Quotient may be really understood after a confused Manner, which may differ from a rational Quotient assigned by a Quantity less than the least Quantity assignable, both as to Excess and Defect. Nor consequently do we deny, but any Division also of incommensurate Quantities, and a Quotient not distinctly effable, may be conceived: nay we willingly allow this, that the universality of the subsequent Argument may appear the more. These Things being noted, repeating the former Hypothesis, I say, if according

to our Definition $A : B :: C : D$, then will $\frac{A}{B} = \frac{C}{D}$. If you deny it, let there be an Excess on either Hand; *ex. gr.* let $\frac{A+X}{B} = \frac{C}{D}$. Let X be multiplied by some Number M , till MX be more than B . Which may be done from that most clear Axiom, that Geometricians assume with *Archimedes*, *viz.* Any Quantity may be taken so often that its Multiple taken so often may exceed any assigned Quantity of the same Kind. It appears therefore that B may be so multiplied by some Number N , that NB cannot be exceeded by MA , but may be exceeded by $MA+MX$, because MX is greater than once B . But because $\frac{A+X}{B} = \frac{C}{D}$ from your Hypothesis, then multiplying both Sides of the Equation by the same Number M , will $\frac{MA+MX}{B} = \frac{MC}{D}$: and again dividing both Sides of the Equation by the same Number N will $\frac{MA+MX}{NB} = \frac{MC}{ND}$. Therefore because it was shewn that $MA+MX > NB$ will $MC > ND$. For when two Fractions are equal, if the Numerator of one exceeds its Denominator, the Numerator of the other will exceed its Denominator also, otherwise they will be unequal, contrary to the Hypothesis; the one being greater, and the other lesser than Unity. Because therefore it is proved that $MC > ND$, but $MA < NB$, it appears that according to our Definition, A is not to B as C to D : which is contrary to the first Hypothesis. Therefore our Adversary is wrong in denying that A divided by B is equal to C divided by D . Q. E. D.

And now from these Examples it evidently appears *First*, that this *Definition* depends upon an Hypothesis

Hypothesis clearly possible *viz.* such as is demonstrated by innumerable Examples, and is not feigned without Grounds, but actually is; or that the Condition of this Definition really agrees with many Quantities. *Secondly*, that this Property is so universally extended, as not to be hindered by any *Incommensurability*, or *Heterogeneity* of Quantities: since neither these, nor their Opposites, *viz.* *Commensurability* and *Homogeneity*, were at all considered in its Application. *Thirdly*, that this Property necessarily flows from Nature, or is intimately conjoined with the specific Condition of the Quantities to which it is attributed, and consequently is not remote from their Essence, as *Proportionals*. For it is always shewn to agree with the Quantities proposed by their Definitions, as so conditioned, or by some principal and essential Properties. *Fourthly*, that this Definition is not barren, nor unprofitable, but the fruitful Mother of Conclusions about Subjects both general and particular. For the whole *fifth Element* depends upon it, and whatsoever is any where proved in the Elements of Geometry about *Proportionalities*. *Fifthly* I add, that neither is it troublesome nor tedious, but begets most of its Conclusions with a great deal of ease. For by it the first and principal *Proportionalities* of Quantities are drawn and demonstrated immediately and directly, without any unnecessary Circumstances. *Sixthly*, that from this Definition are easily enough deduced both those Affections by which others make their Definitions, and the remaining Affections which those draw from their own Definitions; and consequently again, that this Property is most intimately conjoined with the Nature of *Proportionality*. *Seventhly*, I add, because of the Calumny of *Induction*, that no *Induction* appears here; but the Discursus, which is here used, consists altogether of universal Propositions,
and

and flows from universal Principles. Nor do I see how any one, who will but moderately attend to so many clear Examples, can justly accuse this Definition of *Euclid* not only of Incomprehensibility, but even of the least Obscurity or Difficulty: But all Knowledge of all Things seems difficult to a lazy Mind, as far as it requires Attention. This is a common Vice to us, that we desire to live void of Care, and especially to obtain Knowledge without Labour. But what finally hinders but from a just Perception of these Things, notwithstanding the Opposition of some, we may boldly pronounce, that the Mark and Title of the best Definitions agrees with this Definition of *Euclid*? For it most appositely agrees with the principal Laws of a good Definition, which are found agreeable to Reason and Experience. Since it depends upon an Hypothesis most evidently possible, distinguishes its Subject from all others, exhibits an Affection of it as such, necessary, essential, and reciprocal, from whence the other Affections may be deduced; and consequently is useful for drawing Conclusions, and begetting Science; and lastly, since it may be easily, clearly, and directly applied to Things, and transferred to Use: Besides which, I have hitherto scarce observed any other Laws, Conditions and Properties of a good Definition; which because they all agree with our Definition, I fear not to pronounce it very good. This will more plainly appear from repelling the Weapons with which our Adversaries do angrily oppose us, which fly in so thick a Cloud, and are flung with so strong a force, that the present Lecture not being sufficient to receive them; therefore we will attempt them in the next.

LECTURE XXII.

*An Answer to the Objections against Euclid's
Definition of Proportionals.*

IN our last we endeavoured to expound *Euclid's* Definition of *Proportionals*, and defend it with some preparatory Arguments. But because most of the Moderns do either greatly oppose, or quite reject it (some indeed as a Proposition simply false, but more as a bad Definition;) it remains that I clear it from the Accusations they bring against it.

And first of all *Ramus* has taken it in the worst Sense; yet so as plainly to shew that he pronounced unadvisedly, and without a right Understanding of the Matter. *First*, he says it is *very dubious and false*; which indeed is a mere Calumny, proceeding from nothing, but a most gross Error: *viz.* because he does not rightly understand what is meant by *exceeding, falling short, or equalling together* (or *simultaneously*) according to any *Multiplication*. Since *Euclid* most expressly requires it, as a Mark of *Proportionality*, that a *perpetual Simultaneity of Excess, Defect or Equality* in all Respects be proved concerning the *Equimultiples* of the homologous Terms; but because it falls out, that *Quantities not Proportional* do sometimes obtain certain such like *simultaneities*, he therefore accuses *Euclid's* Proposition of *Dubiousness* and *Falsity*; and what can be more spiteful or weak? To produce something parallel from a common Subject: Suppose any one should define or describe a *good Man*, for one who composes and conforms

all his Actions according to the Rule of right Reason; does he weaken this Description because a *bad Man* does sometimes Actions agreeable to Reason, or sometimes acts justly and soberly? Nay it sufficiently distinguishes a good Man from a bad, to say, in a moral Sense, that the former acts according to the Prescript of Virtue constantly and perpetually, but the latter inconstantly and contingently. In like manner also here, a *perpetual Simultaneity* distinguishes *Proportionals* from *Improportionals* which do not obtain it necessarily or perpetually; nor does it any Way hurt our Definition, because it happens sometimes to them. But besides that *Archimedes*, and other most sagacious ancient Geometricians have not built their Demonstrations upon a false Foundation, most of the modern Impugners of this Definition, as such, do oppose it under this Pretence, that it is demonstrable, *i. e.* necessarily true: and consequently *Tacquet*, *Borellus*, and *Hobbs* have demonstrated it from their own Principles, and *Clavius* himself, as to Numbers, from *Euclid's* Principles. So far is this Proposition from being false, or *Ramus's* Accusation from just.

But *Ramus* insists upon these Words; *For Proportion* (says he) *is not accurately enough concluded from that triple Difference, since there is a most false Sophism in that Argument* (but you would do well to shew me where, O *Ramus* :) *An equal Subtense* (you say) *subtends an equal Periphery, a greater a greater, and a lesser a less. Therefore* (*viz.* according to *Euclid's* Definition) *Subtenses are proportional. Which Ptolemy* (you say right) *Conjectures to be false.* But, O excellent Censurer, this Argumentation is as far from the Purpose, as the Heaven is from the Earth. For what Application is here of *Euclid's* Definition? What mention of *Equimultiples*? What here has any Affinity or

Likeness to these, to deduce the *Proportionality* of Peripheries with their Subtenses? For no such Thing either is or can be gathered from our Definition rightly understood. The contrary indeed follows, and is rightly gathered by *Ptolemy* himself from the Propositions of the Elements derived from hence, and from *Euclid's* subsequent Definitions of kin to it.

But lest we should be thought to say this without Proof, we will give a most easy Instance (FIG. X.) Let there be two Arches ZA and ZM, the former a Quadrant, and the latter a Sextant of the whole Circumference. I say the Arches ZA and ZM are not proportional to their subtenses ZA and ZM, according to our Definition. For let the Antecedents ZA be multiplied by the Number *Four*, and the Consequents ZM by the Number *Six*; it is apparent that the *Quadruple* of the Arch of the Quadrant ZA is equal to the *Sextuple* of the Arch of the Sextant ZM, since each Multiple equals the whole Periphery of the Circle. But the *Quadruple* of the Chord ZA is less than the *Sextuple* of the Chord ZM, *i. e.* the Perimeter of a *Square* inscribed within a Circle, is less than the Perimeter of a *Hexagon* inscribed within the same: Therefore, according to *Euclid's* Definition, the *Peripheries* ZA and ZM are not *proportional* to their *Chords*. Which was the Thing to be proved, together with the Weakness, and (pardon the Word) Impertinence of *Ramus's* Instance. In the meanwhile we may wonder at such a licentious Censoriousness as this trifling Talkative Man, not to say worse, is wont to use against the ancient Geometricians.

But he disputes farther, *That should there be no such Sophism* (as indeed I interpose there is not) yet *nothing will be defined in this Definition* (Why so pray?) *for neither here* (says he) *will it be taught*

why they are proportional, but an Alternation of Proportionals will be proposed. Lastly this Definition will teach that the simple Terms are proportional, whose alternate Multiples are proportional. Therefore the Hysterologia is twofold, &c. But with what Eyes has he seen or read any *Alternation of Proportionals* proposed here? Where is found the least Appearance of *Proportionality* of Multiples? I see indeed an *Excess, Defect* or *Equality* of Equimultiples; but I can perceive no Mark, no Footstep of *Alternation* or *Proportionality*. Is not this to treat, or rather dream of Things, in a disorderly Manner? How comes he for such poor Causes and false Arguments to brand those venerable Persons, with Notes of Fallacy, Sophistry, and Absurdity, and defame those Builders, and first Propagators of the Sciences with such uncivil Contumelies; without whom perhaps this mighty Artist at Trifles had had nothing but Fables to apply his wonderful Logic in the Resolution of? Which had been done more innocently and safely, than in inveighing so furiously against such Men. Indeed I can scarce moderate my Indignation, but use him as he deserves, and return those Railings more strongly upon his own Head, which he throws against the Ancients. It would be troublesome to mention what he objects besides, with the like Acuteness and Skill; which plainly proves nothing else but this, that it is entirely different to compose Logical Methods, and to judge of the Mysteries of the Sciences. But some he concludes peremptorily, and with the utmost Assurance, *Wherefore* (says he) *such a Definition is quite taken away from the Mathematics.* I reply, Except it be shaken with stronger Machines, it will continue fixed to Eternity, and never be removed from the Mathematics.

But

But leaving him, let us encounter *Tacquet*, a Man of a more sagacious Perception, who as he engages us more modestly, so, as it usually falls out, more strongly, and with a greater Shew of *Probability*. Let us then hear what he says; *First* (says he) *it is certain, that the Nature of equal Reasons is not explained by that Definition, but only some Affection.* I return *first*, that no Definition explains the *Nature* of any Thing otherwise than by assigning some necessary and reciprocal Affection of it, as is done here. If he can shew any such, I shall not unwillingly give up the Cause; but if he cannot, as I am confident he cannot, then he involves all Definitions in the same Fault, and strikes them with the same Weapon. He who defines a *Circle* from the *Parity of its Radii*, a *Triangle* from the *Concourse of three Right Lines including Space*, a *Square* from the *Equality of its Sides, and Rectitude of its Angles*, what does he else but explain the *Nature* of those Figures from certain of their Affections? *Secondly*, I say, that there neither is, nor can be conceived any such *Nature*, as he feigns and supposes distinct from such necessary Affections or prior to them. To have some such Affection is the *Nature* itself of a Thing, is essential to it, and constitutes it. At least, which is all one, to have a certain Complication of Affections so connected, as every one to imply and necessarily draw along with it the rest, does truly constitute the *Nature* of every Thing. From whence, he, who says a Thing has such an Affection, explains the *Nature* of that Thing. *Ex. gr.* a *Circle is a Figure having equal Radii*, or a *Figure of such a Nature as to have equal Radii*: where *to have equal Radii*, is the very *Nature of the Circle*; or at least *to have equal Radii, and other concomitant Affections* entirely contains and declares the *Nature* of it.

As also to have right Angles at the Circumference subtending the Diameter, or, any other reciprocal Affection, does equally express the Nature of a Circle. They, who imagine or seek for other Natures of Things, do only impose upon, and delude themselves, by pursuing after fleet and vanishing Chimeras, never to be perceived, or overtaken. Therefore *Euclid*, when he exhibited a necessary Affection of *Proportionals*, did abundantly declare and explain their Nature, as much as is usual and capable of being done. And consequently the Fact seems enough for this Objection.

Moreover *Tacquet* pursues us with another twofold Argument; Next, says he, that Property of Multiples is brought, either as an infallible Sign of equal Reasons, that whensoever it is demonstrated concerning any Reasons, we may certainly infer that they are equal; or else that is his Sense, that he would have Magnitudes bearing the same Reason to mean nothing but that their Multiples exceed, or are exceeded in the aforesaid Manner. I answer Both are true; it is both produced as an infallible Sign, and exhibited as an essential and distinguishing Character of *Proportionals*. Which two Things indeed have no real Difference, and do agree with every good Definition. For there is no infallible Sign of any Thing, but its essential Attributes. Every Thing may be stript of all Things, but its essential Attributes, nor consequently can any Thing not essential indicate the certain Presence of a Thing. But our Adversary opposes both separately, in these Words; *Albeit first it must be demonstrated that that Affection is in all equal Reasons, and them alone, that the Equality of Reasons may be certainly inferr'd from it. But that Theorem is not common, which neither Euclid nor any after has demonstrated.* I answer, that here is an unjust and impossible Law fixed upon *Euclid*, and other Authors of Definitions, viz. That they demon-

demonstrate the *Predicate* of a Definition to agree with its *Subjeēt*; which they are neither able nor obliged to demonstrate, but to assume gratis, *i. e.* impose at Pleasure the proper Name of the *Subjeēt* upon the *Attribute*. Is it incumbent upon me to demonstrate the Name of a Circle to agree only with Figures having equal Radii? No surely, but of my own Authority I assign the Name of a Circle to all those, and them only. Just the same Way, at his own Pleasure (tho' not rashly, and imprudently, but for certain just and proper Causes, which I have mention'd more than once) does *Euclid* attribute the Name of *equal Reasons*, to all Reasons endow'd with the said Property, and to them only; he appropriates the Appellation of *Proportionals* to Quantities obtaining that Condition: whence because of this Name of *equal Reasons* and *proportional Quantities* it must justly be thought to agree with all those, and those only. For it is established by a most just and necessary Law, that as it is a *Right* belonging to Teachers of Sciences to impose Names, so Learners are obliged to receive them. There is only one Thing that the Author of a Definition is bound to demonstrate, (*viz.* by Examples clear to the Sense, or by an evident Discursus) which is that the Attribute of the Definition contain nothing impossible or merely imaginary, but that the Things endowed with the supposed Property or Condition, may really exist. As he that defines a Circle from the Parity of the Radii (for I purposely use the most easy and familiar Examples) is obliged to demonstrate nothing else, but that it is not repugnant for such Figures to exist wherein that Property agrees. Which he can most clearly shew from their Generation, by the Circumduction of a Right-line, or otherwise. Thus since it can be very easily and plainly proved, and is every where actually done by *Euclid*, where he applies this Definition to any determinate Subject,

that there are Quantities to which the Hypothesis of this Definition may agree, therefore nothing is required further ; and it is supported by the best Authority, to affix the Name of *Proportionals* to all these Quantities, and to them only.

But because he subjoins, *this Property* to happen to *Proportionals*, that *that Theorem is not common* : I answer, repeating what was heretofore expounded, that in Reality every Definition is a Theorem ; viz. a Proposition demonstrable from other Definitions of the Subject, or from other reciprocal Affections before attributed to the Subject : Also on the contrary, that every Theorem may be formed into a Definition, if it consist of a perspicuous Example, or include a possible Hypothesis. Wherefore because this Property may be infer'd from other Definitions of *Proportionals*, and a Theorem constituted from thence ; nothing derogates or hinders, but that it may enter a lawful Definition : as neither permutably, because, as has been shewn from this Definition, the Property may be deduced, from which *Tacquet* himself rather defines *Proportionality* ; and consequently because its Definition may put on the Form of a Theorem, does that any Way hinder, but its Definition ought to be thought just and lawful ; tho' other Things perhaps may hinder. But if, by his saying the Theorem is not common, he intimate as tho' this Definition is drawn with difficulty from the Definition and Principles laid down by himself, he does nothing to the Purpose. For it is not requisite to the Perfection of a Definition that the Property applied in it do easily follow from other Principles however posited. For by the same Means will his own Definition merit the Title of a Theorem not common, because it will be no easy Thing to derive it from all other Definitions ; in particular not from our own. Nor next is it strange that this Theorem is demonstrated neither by *Euclid*,

clid, nor any other, because they have assumed it for a Definition, and accounted it as a Principle subservient for demonstrating other Theorems; for whoever attempted to demonstrate his own Principles? Wherefore I make no Account of *Tacquet's* Discourse elsewhere in these Words; *The Demonstration indeed*, says he, *of which Business, since it is sufficiently difficult and prolix, as anon we shall find in Reality; it will easily appear that Euclid has acted preposterously, who would take the first and fundamental Property of the Equality of Reasons from this Property of Multiples hitherto indemonstrated, whose Connexion with the Equality of Reasons is so remote and obscure.* Which Words I shall so retort upon the Accuser, as I doubt not, but cast the preposterous Judgment upon him who makes it a Crime to have put an indemonstrated Property in his Definition; as if the Property of the Subject in a Definition, could without manifest Contradiction be demonstrated by him who defined the Subject by it. For as it is put in the Definition, it is assumed to be the first Property of all; but as demonstrable, it supposes some prior Proposition, and therefore cannot be the first. Wherefore our Master has not proceeded in a *preposterous* but a *most direct Order*. But when he exclaims that the Connexion of this Property with the Equality of Reasons is remote and obscure, he notoriously begs the Question; for certainly *Euclid* supposes it to be most manifest, and therefore makes a Connexion of that with this in defining this from that.

But he goes on, as he thinks, to press hard upon us; *If*, says he, *Euclid, by Magnitudes having the same Reason, would only understand that their Magnitudes exceed, or are exceeded after the said Manner, we shall be secure of the Things taken in the Sense of the Definition concerning the Verity of the Theorems, but it will not appear to us from the Force of Demonstrations*

strations concerning the absolute Equality of Reasons. To which place I have nothing more to answer, than that I am utterly ignorant what *absolute Equality of Reasons* he here dreams of, as pre-existent and distinct from the Affections by which an Equality of Reasons may be defined, which is here supposed without any Foundation. An *Equality of Reasons* (like all other Subjects consider'd in the Sciences) is no otherwise found than from its Agreement with their Definition, whether *Euclid's* or any other Definition, that may be reckon'd lawful. Reasons are therefore most absolutely and formally equal, because they have the Property expressed in their Definition; wherefore since this Property is demonstrated in *Euclid's* Theorems to agree with any Quantities, an Equality of Reasons at the same Time appears to agree with them; as when a Parity of Radii is shewn concerning any *Figure*, it is demonstrated that that is a *Circle*.

The *Epiphonema* therefore is weak and vain, with which he closes these Argumentations. *Howsoever then*, says he, *that Definition be taken, the Demonstration of the fifth and sixth Books do totter so long as it is not demonstrated that a true Equality of Reasons is connected with that Property of Multiples.* According to which Sentence indeed all the Demonstrations of every Science will totter. For if it must always be demonstrated that the Properties attributed in Definitions are connected with their true Subjects, there will be no End of demonstrating, or rather no Beginning, but every Argumentation must run backward *ad infinitum*. Besides since himself has assigned a Definition of *Proportionality*, the same Thing may be objected against him, in the same Words; so that himself is bound by his own Law to demonstrate the Property, which he assumes to agree with equal Reasons; *viz.* from some prior one, and that again from another, till being wearied

ried with the endless Labour, he shall own his Error.

In Sum, I observe universally of those Reasonings of *Tacquet*: *First*, That he every where begs the Question, and commits vicious Circles, arguing thus, *A Property is not proximate, but remote, because it can be demonstrated, i. e. because there is another nigher; another is nigher, because it may be demonstrated that this Property constitutes not an Equality of Reasons (i. e. cannot enter its Definition) because it differs from it, is not clearly connected with it, or is very much removed from its Nature.* And so every where.

Secondly, I note that neither he, nor most others, as far as I can judge, do sufficiently perceive the *Nature* of a Definition; by whom nothing is really done, but a Name imposed upon a Thing, as it is the Subject of an Affection evidently discovered by Sense or Reason: but they devise I know not what abstruse *Natures, Essences and Formalities*, which can never be brought to Light. By which, if we search the Thing to the quick, it will appear that they understand nothing but some imperfect and indistinct Conceptions, or Significations, answering to the customary Name of the Thing defined, which are not to be received in the Sciences, and are unfit for Demonstrations; to which consequently no Definitions are requisite; nay Definitions are to be formed by secluding and banishing those, and substituting for them certain Distinct and clear Ideas of Things; appropriating Names to Things, as far as they are subject to certain Affections conspicuous to the Sense, or to the Understanding.

I observe *Thirdly*, That *Tacquet*, led by such Arguments, has assigned a Definition of equal Reasons very vicious and useless. For he says, *Reasons are equal, when the Antecedent of the one contains, or is contained in, its Consequent in the same Manner as*
the

the Antecedent of the other does contain or is contained in its Consequent. Which Definition only begets a gross and confused Notion of *Proportionality* unapt and unsuitable to beget any Conclusion. For the Phrase, *to contain in the same Manner*, is dubious and obscure, nor is it really limited to signify any Thing distinctly, but by another Definition. There are many *Manners of containing*, which may in some Sense be said to be the same; *viz.* every greater Thing contains a lesser *in the same Manner of Excess*; and again any two unequal Things respect one another *in the same Manner of Inequality* with two other unequal Things. Therefore except a Mark be shewn by something more strict and certain, what it is *to contain after the same Manner*, any Identity of Manner may be here designed, and consequently we shall be ignorant or Uncertain what an Equality of Reason is.

But to pass by other Inconveniences to which this Definition is subject, one only Exception remains more plausible than all the rest, which I fear it will not be in my Power to remove; not that it carries any great Force along with it, but because it is favour'd by the Prejudices of many, and encourages Idleness. It is proposed by him in these Words; *Lastly, that all Things might consist with one another, yet that Labyrinth of Multiples has always been displeasing to me and others, and has always created too much Trouble to Learners, whose Minds are for the most Part so embarrassed by it as hardly to be extricated.* Which Capital Crime that I may in some Measure remove out of the Way, I answer, *first*, we are to seek from what Causes that Perplexity so discouraging to many can arise which they pretend; whether from the Thing itself, which can admit no Exposition more commodious or clear; or from the Heedlessness of Interpreters, who have not illustrated this Definition with Examples sufficiently per-

perspicuous ; or lastly from the Default of the Learners, who imagine with themselves that the Difficulty is insuperable, and so are discouraged before they apply their Mind to it. If any of these Things be the Occasion, as indeed I am persuaded they all contribute something towards the making this Definition seem more perplexed, the Author is to be pardon'd, and the Blame imputed to other Causes. The Thing itself cannot be quite excused, which, because of the Incommensurability of Quantities, labours under some peculiar Difficulty ; so that no Body allows it not to be difficult to find out some Affection equally congruous with all *Proportionals*, or to exhibit some Definition comprehending all Equalities of Reasons. Which also appears from hence, because hitherto it seems to have befall'n the most famous Persons who have attempted to apply a Remedy to this Disease, that either they have performed nothing at all sufficient, or they have walked in Ways more prolix, and not less intricate and perplexed ; or at least they have deliver'd Methods worthy of some greater Blame, and consequently the Thing itself is too stubborn to be handled in a very easy and ready Method. Nor do I wholly excuse Interpreters from Blame, not even *Clavius* the best of them, who tho' he has both explained this Definition well, and strongly defended my Opinion, yet he seems not to have illustrated it enough with clear and apposite Examples. For the Examples he brings do rather explain the Sense of the Words, than represent the Possibility of the Condition supposed, and its true Existence in Things, which especially recommends as well as illustrates any Definition ; so that they confound the Imaginations of Learners, with their being too universal. Perhaps also he is not express and clear enough (which is itself another Occasion of Confusion) to the Intent that he may prevent Learners from imagin-

2

ing

ing that an *Induction* is required, or that infinite Tryals of Multiplications must be run over in the Mind, at which it is no Wonder if they be also confounded and discouraged; though no such Thing is here requisite, as we have often taken Notice. And as to the Learners it appears they are generally too much wanting to themselves. For though the Words of this Definition are most clear, and void of all Equivocations, yet how few are they, who can have so much Patience as accurately to examine the Sense of three Lines? But I dare lay a good Wager, and almost engage my Word and Promise, that to him, who seriously reads over this Definition, and gives diligent Application to the last Proposition of the sixth Element, it will not appear perplexed, intricate, or difficult. These Things being premised, I answer the Words of *Tacquet* by plainly denying that here is any *Labyrinth* to render the Thing more intricate, than it is in itself, which a little Art of the Expounder may not extricate, and from which a small Share of Attention may not free the Learner. I add, where there is no double Meaning in the Words, no Prolixity, and where there is always applied a most direct Discursus (all which Things are found in this Case to concur,) there can be no great Obscurity or Difficulty. This Definition is especially used in a few Propositions of the fifth Element, but every where, as I remember, they are demonstrated by it directly and immediately. And where it is accommodated to particular Subjects in the other Elements, or in other Books of Geometry; it always concludes in the same most simple and direct Manner, and not as others do in their Methods, indirectly, or by reducing the Thing *ad absurdum*; which Manner of demonstrating, as all acknowledge is very obscure and ignoble. Moreover if with *Tacquet*, we may assume what we please,

please, as clear by its own Light, and (what the ancient Geometricians studiously avoided) heap together an immense Number of Axioms, indeed the Thing may be often very compendiously handled, but yet for all the Brevity it gains, and some Evidence arising from thence, it loses as much of its Strength, which is of much more Concern, and ought to be more regarded in the Sciences. Of which, as I remember, we have already treated. Wherefore *Tacquet* has no Reason to boast of the Shortness, or Evidence of his Method: especially since he has given no Definition of *Analogy*, or what is next to none, and has accommodated his Propositions, which are either taken *gratis*, or, as himself thinks, demonstrated, to an uncertain Subject. But we now seem to have sufficiently repelled this considerable Adversary.

Mr. *Hobbs* follows, whom we will very readily dispatch, because in the preceding Arguments, we have suggested Solutions, which may be adapted to his. Let us hear what he says, *But it is impossible to find four such Quantities by this Definition, because a Multiplication by all Numbers is impossible, since they are infinite; This is not then a Definition, but an Hypothesis.* To this Discursus I premise, that this Philosopher mistakes *Euclid* to have given him so much Labour in this Definition, as if he treated of the *Generation of Proportionality*. He neither thought nor aimed at any such Thing, but only to assign the *distinguishing Property of Proportionality*; as when he defines a Circle from the Parity of its Radii. Where perhaps it may be worth the while to take notice by the by, that though commonly such Definitions are best, which express the *Generation* of Things (nay indeed strictly speaking such only are good, when the Things defined are immediately, and as it were originally of themselves capable of *Generation*) yet such
such

such Definitions are not agreeable with some Things, *viz.* with those that are not *generated* by themselves but, as secondary Affections, result from the Constitution of other Things already *generated*, and flow from their primary Affections. *Ex. gr.* He that undertakes to define the *Focus* of a *Parabola*, or *Ellipsis*, after he has observed that such a Property is in a *Parabola* already constituted, *viz.* that all the Radii (or Rays) parallel to the *Axis* are reflected from the Curve Line of the *Parabola* to a certain determinate Point in the *Axis*; and that such an Affection agrees with an *Ellipsis*, *viz.* that the Radii proceeding from one certain Point in the *Axis* are reflected from the Ambient of the *Ellipsis* towards another Point in the *Axis*; this Property, I say, being known (which flows from other primary Properties of those Lines,) he may best define the *Focus*, not from its *Generation*, which would be a Thing of infinite Labour, but from the *said Property found*, *viz.* to be a Point in the *Axis*, into which all Rays parallel to the *Axis*, or proceeding from one certain assignable Point in the *Axis* reflected in the Manner shewn, are gathered or do tend. So *Proportionality*, since it is not a Thing subsisting primarily, nor immediately generable, but a certain *Affection* resulting from some predeterminate Condition of Quantities, it is scarce possible, at least not expedient, to be defined by any *Generation*. However it will be manifest to any one, who examines the Words of this Definition, that no *Generation* is here really hinted at, but only some Property often agreeing with four Quantities, which, from the Hypothesis of having that Property, are said to have the *same Reason*, or be *Proportional*.

I answer then to *Hobbs's* Exception, that tho' it be allowed to be altogether impossible by this Definition to find four proportional Quantities (as it is impossible

impossible from the Parity of Radii to find a Circle, *viz.* by attempting and trying whether or no the infinite Radii in the proposed Figure be equal) yet that which is here solely intended and is sufficient, it is very easy to demonstrate, that this Property universally agrees with some Quantities (*ex. gr.* with two Parallelograms of the same Height and their Bases;) as also from certain given Conditions, it will be easy to shew that some Figure has all its Rays equal. For this no Multiplication is required by all Numbers, no infinite Labour, as often has been shewn. Therefore this Objection effects nothing. But farther, *This*, says he, *is not a Definition, but an Hypothesis, indeed a true one, but not a Principle, because it is demonstrable, and is demonstrated by Hobbs.* I answer *first*, that neither he, nor any other has demonstrated, or can demonstrate, that those Quantities which obtain the Property noted in this Definition ought by *Euclid* to be called *Proportionals*, or such as have the *same Reason*. For this solely depended upon *Euclid's* Will and Pleasure. It is not therefore altogether true that this Definition was demonstrated by *Euclid*. *Secondly*, I say, it is no Hindrance to any Definition, that the Property by which it is defined can be demonstrated concerning the Subject defined by some other Property; otherwise it would be no good Definition. Some Things indeed endowed with many Affections may be conveniently and rightly enough defined many Ways. An Instance may be brought from the *Conic Sections*, which since they may be generated various Ways (*viz.* by the Dependencies and different Compositions of Motions; by the Sections of various Bodies; and by the manifold Methods of designing infinite Points) and since they obtain infinite Affections intimately connected with them, and on the Part of the Thing equally original, and equally depending

upon clear Hypotheses, they are wont to be defined many Ways; therefore I think none of them is to be rejected, though any one being chosen as the *first*, the remaining Properties may follow from that, and consequently are demonstrable. From whence it appears by the Way, that the Principle delivered by *Aristotle* in his *Topics* is false, upon which our Adversaries seem chiefly to depend, *viz.* (a) *That it is not possible for more Definitions than one to be of the same Thing.* For it is possible for every Thing to have as many Definitions, as it has reciprocal Properties clearly expounded, and apparent to us. Therefore Mr. *Hobbs* says nothing to the Purpose against our Definition.

I shall only recite what the great and learned Person (b) says concerning this Definition in his *Arithmetic*, who partly favours, and partly opposes it. *We*, says he, *have thought fit to omit this Definition in our Demonstrations, though indeed true, and apt enough for Euclid's Purpose, nor do we accommodate Proportionals to this Criterion. But because it seems somewhat perplexed, and perhaps not perspicuous enough, especially to Learners. Nor indeed does it so immediately respect the Nature of Proportionals, as some Affection of them, which is sufficiently remote.* These are his Arguments: Which or the like having been already sufficiently considered, there is no Cause why we should dwell longer upon them.

We have now come to the last Push, *viz.* to the most subtle *Borellus*, the most bitter Adversary, and who above others has done this Thing extraordinary, that he has produced out of his own Store a new Doctrine of *Proportionality*, indeed elegant and solid; yet in my Opinion not on all Accounts to be preferred to this of *Euclid*. But

(a) Topic VI. 5.

(b) Cap. 35.

neither after a diligent Examination of his Disputation, do I find any Thing at all of Moment derogating from our Definition, to which abundant Satisfaction seems not to be made in what we have said already. Most Things rather touch *Clavius* than *Euclid*; and I do not look upon it to be our Business at present to defend *Clavius's* Words, howsoever able. But since the present Dissertation has already exceeded its Bounds, whatsoever *Borellus* has produced new and worthy of Consideration, I leave to be examined hereafter, when I begin my Animadversion upon the Methods of him and other Moderns. In the mean Time, let it suffice to have proceeded so far.

L E C T U R E XXIII.

An Answer to Borellus's Objections, and of the Insufficiency of the Definitions of Proportionality which are substituted in the Room of Euclid's.

I N the last Lecture we have endeavoured to repel the Attempts of some principal Adversaries against *Euclid's* Definition of *Proportionals*. *Borellus* remains, who, in my Opinion is by far his most considerable and powerful Opponent; and the more so, because he has devised of his own Head a new Method of resolving *Proportionality* in vain attempted by others, which we readily own to be a Work very elegant, laudable, and not unuseful; it being both pleasant and profitable to handle the same Subjects various Ways, and deduce the same Theorems from different Principles; yet, I think,

he was more happy in framing his own, than in opposing the common Method, as we shall next attempt to shew.

Let us hear what he objects, *It cannot, says (c) he, be said in Reality that the Property assigned declares the Nature of the Thing, and distinguishes it from every Thing else: so far from it, that it renders a difficult Thing more obscure.* So he judges, but, I suppose we have shewn in what went before, that these Things are spoke at Random, viz. that the Nature of *Proportionality* is nothing else but to have some such Property, which other Properties follow; and consequently that its Nature is as abundantly declared in this Definition, as it can be in any other: and that this Property distinguishes *analogous* Things from Things not *analogous*, since *Analogy* reciprocates with it, and to be *analogous* signifies nothing but to have this Property, at the Designation and lawful or reasonable Pleasure of the Definient. Lastly, I deny that the Thing is rendered more obscure by it: For also (as himself confesses in express Words) the Words of the Definition do expound without Ambiguity, what such a Property is: And (I add) it most clearly appears that it exists in very many Things; also its Application is not difficult, as Experience plainly shews; and nothing hinders, but the Name of *Proportionals*, or some other may be attributed to *Quantities* having this Property; at least no Obscurity can arise from the Assignment of that Name. In what then pray does this Obscurity consist, where is it, or from whence does it result? Why it is no where at all. Except we dream of I do not know what mysterious Nature of *Proportionality*, which is prior to every Property entering that Definition.

(c) Pag. 125.

But

But he subjoins the Reasons and Foundations of his Opinion, *It is unknown*, says he, *whether four Quantities having such an Affection can be found in Nature; because if infinite Equimultiples of the Antecedents be compared with infinite Equimultiples of the Consequents, they must exceed together, fall short together, or be equal together.* I answer, this is not unknown, because it may be shewn by clear Examples, that there are many four Quantities endowed with the said Condition. And if there were not, this Definition could by no Means be applied to Use. For as often as it is applied, so many Examples of Quantities having this Property are added to the Number. It is the same Way unknown, that there is such a Figure as has equal Radii, till that is made plain to Sense by Generation, or to the Mind by some Discursus sufficiently evident. Therefore this first Argument is of no Force.

Again, *Those infinite Comparisons*, says he, *cannot be comprehended, and therefore this Affection will not be most evident, as that ought to be, which constitutes the Principle of a Science.* In the first Place, I admire that such Arguments are used by a learned Man; then (not to repeat what I have before answered to the like Arguments) he enquires whether or no Experience teaches, that it is easiest demonstrated by *Euclid*, *Archimedes*, and most other Geometricians, that this Property agrees with many Quantities, *viz.* Triangles and Parallelograms of equal Heights with their Bases; also Pyramids, Prisms, Cones, and Cylinders with their Bases; Circles and Spheres with their similar Sectors; Angles with the Arches on which they stand; Spaces run through by an equal Velocity with their Times; the Moments of Weights with their Distance from the Center of a Balance; and innumerable such like. How then can it be *incomprehensible?*

condly, I say, here is no Infinity of Comparisons supposed more than in any general Proposition, where the Universality of the Terms supposes Infinity. For that which is reckoned in Definition by *any Multiplication*, what else does it intimate but the Universality of the Condition laid down; proved not from a Viewing of all the Particulars, or any inductive Inference, but from an universal Argumentation? It is only required that all the *Equimultiples* of the Antecedents be in such wise affected towards all the Equimultiples of the Consequents; be in such wise, I say, affected, *i. e.* obtain the same Kind or Manner of Reason, Excess, Defect, or Equality. If any Infinity be here *incomprehensible*, also all Theorems of all Sciences because consisting of universal Terms, must be equally *incomprehensible*. Nor will the Proposition be comprehensible, *Every Man is an Animal*, because the Property of Animality is affirmed in it, which may agree with innumerable Men. *Thirdly*, the very Application of this Definition most manifestly refutes this Instance, which only proceeds by substituting any one indeterminate and arbitrary Multiplication of the Antecedents, and one of the Consequents for all their Multiplications which can be imagined; entirely the same Way as all other universal Propositions are wont to be applied. Here no Infinity is discovered, no Ambages, or idle Circumstances, but the most simple Argumentation. Neither therefore does this Reason affect any Thing.

But *thirdly*, he says, *Though hypothetically it be granted, yet it is unknown, what ought to be gathered from that Ambages of infinite Comparisons.* I answer that there is no need of any Thing to be granted *Hypothetically*, for it may be asserted positively, it may be wrested whether you will or no, that there are really Quantities endowed with such
a Con-

a Condition, as we have often shewn. Next, I ask, what he means, when he says, it is unknown what ought to be gathered? Here is not any Thing gathered; but at least, it happens, as it uses, in every Definition, a Name is imposed upon Quantities endowed with some Condition or Property, viz. the Name of *Proportionals*, or Quantities having an equal Reason is imposed upon Quantities so conditioned or affected. From which it is afterwards gathered, if at any Time it appears by Argumentation, or otherwise, that this Condition agrees with any Quantities, that those Quantities are Proportional.

But, he again makes a Noise with the *Ambages of infinite Circumstances*, when no such appears. For he insists farther, *For neither Clavius himself could expeditely and by the Light of Nature gather Proportionality from the Affection of Equimultiples in Commensurable Magnitudes, but he was forced to demonstrate this in those four Propositions of his own. But how will that be a most evident Affection, which cannot be accepted in Commensurable Magnitudes without Demonstration?* I answer, to the End that a Property may rightly enter a Definition, it is no Matter how it is, or may be demonstrated from any other presupposed Property; otherwise, as has been shewn, no Definition is good; for all may be thus demonstrated. *Secondly, Clavius deduced this Property from another Definition of commensurable Proportionals, not indeed in four Theorems, but in one of four, and that not very intricately or prolixly demonstrated; which I suppose he did not, because it was necessary to demonstrate that Property to make it reciprocate with this, or manifest its Evidence, but to shew the Consent and Connexion of this Affection of Commensurables with the other Affection which is well known. For the performing or effecting of which, he prejudices*

nothing of this Property from elsewhere by Examples of a known or knowable Evidence. Moreover, *thirdly*, we will allow him this, that albeit this Affection of Commensurable Quantities, as such, having the same Reason, be not the most noted; yet it is no Hindrance, but it may be the most noted of the general Affections agreeing with all Proportionals both commensurable and incommensurable; and Experience seems to persuade us that it really is most known, because, though many have attempted it, yet no one that I know of has assigned any genuine Property more known. Nay lastly the Possibility of no Hypothesis can be more evident than that which this Definition depends upon. Therefore no evident Affection of Proportionals can be demonstrated; nor therefore does this Reasoning succeed.

But at length he gives *Euclid* a most cruel Blow, so that he not only vanquishes him (as he thinks) but condemns him out of his own Mouth. *It was judged*, says he, *insufficient by Euclid himself, when he again defined commensurable Proportionality* (the Proportionality of Commensurables he would say) *in his seventh Book.* I answer this Scandal by utterly denying that *Euclid* therefore judged this his Definition insufficient, because he uses another in the seventh Element; for if himself had judged this insufficient, he would not have used it at all, but either have given none, or have investigated another. To publish Things not approved, much less Things disapproved by himself, was neither agreeable to *Euclid's* Genius, nor his Intent; as if so knowing and prudent a Person would undervalue his own Work with insufficient Principles. On the contrary rather because he found the Definition of the seventh Element not to agree with every Kind of Proportionality, as being only adaptable to the Proportionality of Commensurables;

rables ; and found this to agree with all universally, therefore when he here entered upon a general Treatise of *Analogy*, rejecting that, he rightly embraced this. But he applied that (I will not say after or before) to commensurable Proportionals, not so much for the sake of Necessity as Convenience, that he might seem the simpler and easier to a vulgar Capacity with Respect to that particular Subject. Nor is it much to be wondered at, that he chose the most simple Property for determining numerical Analogies, since he undertook to treat of the Theory of Arithmetic separately and independently from others, though it agreed not with other Analogies, nor was sufficient for the general Doctrine of Proportionalities. Albeit for a full Defence of *Euclid* we might prove that it is lawful and sometimes expedient (for Variety and Facility's sake,) to raise particular Doctrines from particular Principles (however opposite it be to the common Rigour of Logic) but this being beside the Question we will not now touch upon it. Let it suffice to have shewn, that, as our Adversary pretends, it does not follow from hence, because *Euclid* has elsewhere accommodated a particular Definition to a particular Subject, that therefore himself has disapproved, or judged insufficient, this his general Definition adapted to a general Subject.

From all which it appears that the Conclusion, which *Borellus* subjoins, depends upon weak Premises ; *Therefore*, says he, *it is certain that the Property of the sixth Definition of Proportionals is obscure and difficult, because it not only evidently declares the Nature of incommensurable Proportionals, as does the twentieth Definition of the seventh Element ; but again, which is strange, he does not explain those Things, that we have required the Foreknowledge of concerning the Thing itself to be defined.* (I
interpose,

interpose, as has been often inculcated, that there is no such Thing as a Nature of Proportionals prior to the said Property, nor is it needful for us to know any Thing before that Definition concerning them, at least distinctly and certainly. But he goes on, *For from hence, because four Equimultiples of Magnitudes have that Condition of Excess or Defect, it is not perceived when, or how, they are Proportionals, if the Antecedents do together exceed, or fall short of their Consequents, neither if the Excesses be equal to one another, or no.* Which Words of *Borellus* seem very obscure and ambiguous; but whatsoever they signify I am certain they can no Way hurt us. For from hence, because four Equimultiples of Quantities have that Condition, it is plainly perceived that the Name of Proportionals agrees with them, nor is it any Matter, what else is perceived.

There remains one Objection to be removed after all These, which is the most weighty of all the rest, if it do but depend upon a true Supposition. *Nor finally (says he) can the least Knowledge be gathered from the said Property, viz. that to make four Magnitudes proportional, when the first exceeds the second, the third Magnitude must necessarily exceed the fourth, as Clavius confesses in Prop. XVI. lib. 5. Elem.* I answer, *First*, That this Confession seems to be falsely fixed upon *Clavius*, for in the Place cited I can find no such Thing. *Secondly*, How has *Euclid* demonstrated, if not from that Property, having premised no other Definition of Proportionals? Certainly he has demonstrated by it, though not immediately. And who knows not that in most Demonstrations the Property of the Subject is not deduced immediately from its Definition? it being sufficient to be done mediately by other Properties before derived from the Definition of the Subject. *Thirdly*, I add, though *Clavius* did

did not gather that Knowledge from this Property, yet it may be gathered, immediately and not difficultly : Which I thus prove by an indirect Discursus. Let $A : B :: C : D$ according to our Definition, and let $A \not\propto B$, then I say $C \not\propto D$. If you deny, let $C =$ or $\propto D$, and let all the Terms be multiplied by any one Number M ; then because $A \not\propto B$ by the Hypothesis, also $MA \not\propto MB$; and because $C \propto D$ will $MC \propto MD$. Therefore according to this Definition A will not be to B as C to D , which is contrary to the first Hypothesis ; and our Adversary wrongly denies that by supposing $A \not\propto B$ therefore will $C \not\propto D$. So the said Knowledge (as he calls it) is deduced from our Definition, and the Objection of our Adversary answered.

Who then (says the Objector) will say that the sixth Definition is good and a Principle of Science, if it affords a Knowledge obscure and imperfect? To put an End to this prolix Disputation, I deny not myself to be one who will positively affirm (whatsoever he or others say in Contradiction) that it is one of the best of Definitions, a Principle most suitable to this Science, suggests a Knowledge most evident and perfect, and consequently, in my Opinion, overthrows all the Assaults of its Adversaries. And therefore I defend Euclid's Definition and the Doctrine of Proportionality depending upon it, as much by the Probability of the Thing, as out of a Reverence to Antiquity.

In the next Place it follows for me to dwell a little (as I promised) upon the Definitions and Methods substituted by others ; by which the Excellence of *Euclid's* Doctrine will farther appear, with what Necessity he is bound, and for the avoiding of what Inconveniences he is led to own the Property so often mentioned.

The *first* is the Method of those, who think a *Similitude or Identity of Respect* to be the most known Affection of Proportionals by which it ought to be defined. According to which they imagine that some principal Propositions of the fifth Element are to be put for Axioms, because they are perspicuous from their own Light, and need no Proof; and therefore they deduce the other Affections of Proportionals from those. That learned Man *Jobannes Benedictus* is long ago said to have embraced this Opinion; which (or at least something like it) the most acute *And. Tacquet* has very lately reduced into a Form and embellished. Which Method is accused of Insufficiency by *Borellus*, and in my Opinion labours under many Defects. As *first*, in such Definitions a foolish Tautology seems to be committed, and Propositions altogether identical put for Definitions; as in this, *Quantities obtain the like, or the same Reasons, which have like Respects in Quantity; i. e.* (for what else can be here meant?) *which have the like or the same Reasons.* Is not this to define a Thing by itself? Is this to explain the Nature of the Thing proposed, or to lay down a Principle of Demonstration? At least, which is all the same, This seems to be nothing else, but to define by a Genus alone, without applying any Difference, in this Manner, *An Identity of Reasons is an Identity of Respect. Those Things have the same Reasons, which have the same Respect:* Do such Definitions, I beg, deserve to be accounted perfect? *Secondly*, a *Similitude or Identity of Respect* are Words very equivocal, and of an uncertain Signification, impressing no distinct Conception on the Mind of the Hearer. For there are many Species, and many Degrees of *Similitude and Identity.* Therefore except some further Distinction be invented (*i. e.* except some Affection be applied, which is more known, and more

particular than this) nothing will appear from this Word. Wherefore Definitions consisting of such lax Terms explain nothing, are unprofitable, and not at all scientific. *Thirdly*, it can hardly be comprehended or explained in what Manner incommensurable Quantities respect one another; and therefore it cannot be perceived immediately what it is for them to respect one another, in a like or in the same Manner, nor when they are affected with such a Similitude of Respect. Thus far *Borellus* seems to oppose *Tacquet*; from whence it follows, *Fourthly*, that they who proceed in this Method do neither rightly assume Axioms, nor demonstrate Theorems concerning *Proportionals*. For how can any Thing be assumed or proved to agree with *Proportionals*, when it does not yet appear, or is not clearly conceived, what it is to be *Proportional*? Wherefore this Method has no Foundation. Not to insist upon this, that to take, and as it were beg many Things *gratis*, or indemonstrated, is derogatory to the Dignity of Geometry, and introduces too great a Licence into the Mathematics. To which I add *fifthly*, that such Definitions cannot be adapted to particular Subjects, but the *Proportionality* of such Subjects is demonstrated by intermediate Conclusions, and those depending upon Arguments sufficiently prolix and intricate. As will appear to any one who looks into *Tacquet's* Demonstration of the first or last Proposition of the sixth Element. The Definition of *Proportionals* there cited does not appear, but another Proposition of *Tacquet's* that he elsewhere proves in a long and indirect Discursus. Which seems a certain Sign to me of the Unaptness and Imperfection of the Definition laid down, and that the Method is not scientific. To all which Defects does *Tacquet's* Method seem obnoxious, none of which can be objected against the Doctrine of *Euclid*; where
nothing

nothing is trifling, ambiguous, or incomprehensible, but all Things proceed directly, are supported firmly, and the fewest Hypotheses are supposed; and lastly (which is the best Judgment of a most excellent Definition) where Analogies of particular Subjects are derived out of its very Bowels by an immediate and direct Discursus; as will appear to any that consults all its Applications in the Elements, or elsewhere; and particularly the Propositions alledged in the sixth Book.

But I here note by the Way, as to *And. Tacquet's* Method, that, in my Opinion, he would have done far better if he had defined *Proportionals* by that Mark of *Proportionality*, which he brings, and in some sort demonstrates; and if by the Help of that Definition he had demonstrated the other Affections, which I judge (as himself professes) he was able to do. For by so doing he would have emulated *Euclid* and have proceeded in a *scientific* Way; he would have avoided most of the Inconveniences we have mentioned, and might have been defended the same Way with *Euclid*. To which I exhibit this cognate and seemingly easier Affection of *Proportionals*, on which such Definition depends, *viz. Quantities are said to be proportional, when the Antecedents are equally contained respectively in the Equimultiples of the Consequents, or the Consequents in the Equimultiples of the Antecedents; or when those may be taken just so often from these, or the contrary.* From which Definition it would not be difficult to raise the whole *Doctrin* of *Proportionals* in a Procedure very like *Euclid's*, but in my Opinion by no Means more short and clear. Against which however all may be objected, that has been objected against *Euclid's* Method, and perhaps something besides from the Incommensurability of the Quantities, from whence *Euclid's* *Doctrin* is most clear: Wherefore I

do not think it worth the while to innovate any Thing.

Having dismissed *Tacquet* and his Fellows, I will give a Glance at Mr. (a) *Hobbes's* Method, who thus defines *Analogy*, (as he thinks very accurately) *A Geometrical Reason is the same with a Geometrical Reason when the same Cause producing equal Effects in equal Times may be assigned determining the Reasons of both.* Concerning which Definition I cannot forbear saying, that if any one turn over all the Writings of both the Ancients and Moderns, I believe he will no where find any Thing, which is undertaken to be illustrated, to be more obscure, or to labour under more and more unpardonable Errors. For it is both hard and difficult to be understood (in my Opinion indeed it is not perfectly understood by its Author,) and contains Things very much from the Purpose; and I do not know whether it can be accommodated to any Subjects, at least to very few, the whole Doctrine which is built upon it being so weak, confused, and preposterous (also in some Things of great Moment, false) that I never saw any Thing like it performed in the Mathematics. While I am examining this (which indeed is rather a *Physical* than *Mathematical*) Definition, I find Nothing that I can approve, or scarce any Thing that I can disprove, consequently it contains no Explication or Evolution. It explains not what it is for a Reason to be determined by some Cause, which is sufficiently obscure of itself. It is not apparent why it puts in *the same Cause*, since often even the homogeneous as well as heterogeneous Terms, of particular Reasons are produced by different Causes, and consequently do seem determinable by no Causes: Nor does it appear why

(a) *De Corp.* 13. §. 6. *Dial.* 2. p. 49.

that determining Cause is by a strict Law confined to act uniformly, or to produce *equal Effects in equal Times*, since the Reasons of Quantities produced by any unequal Impetus may be equal; therefore here is nothing explained. Again it cannot be conceived why a particular Consideration of Times should intervene with a general Exposition of equal Reasons: Certainly these can be no Way necessary to *Analogy*. *Ex. gr.* When I say two Quantities are proportional to their Equimultiples; what mention, I ask, can there be of any Cause producing equal Effects in equal Times, unless very impertinently and out of the Way? When I say a Sphere and its Circumscribing Cylinder are proportional to eight Ounces or a Pound Troy, do I speak of performing equal Effects in the same Times to determine those Reasons of Bodies, Weights, or Numbers? Nay, even when I am desirous to shew that two Times may be proportional to two Spaces, what Cause performing equal Effects in equal Times will ever determine those Reasons? Will the Reason of the Terms proposed be determined by these or by other Times? But I am hoodwinked, and grope in Obscurity.

Neither as to the Application of this Definition, do I find any Thing but mere Darknes, Confusion, and Discord. The first Proposition founded upon this Basis, is as follows. (FIG. II.) *Let there be two Lines AD and AG described uniformly from a moveable Point A; then all the contemporary Pairs of their Parts will be proportional to one another; i. e. if AB and AE, or AC and AF, be described in the same Times, then will AB and AC be proportional to AE and AF, or AB. AC :: AE. AF.* Which he thus infers from this Definition, if we represent his Reasoning more succinctly and clearly: Because the Velocity in AD by Reason of the Uniformity of the Motion, is always the same, there-
like

fore the Reason of AB to AC is determined from the Difference of the Times alone. Also from a like Cause the Reason of AE to AF is determined from the Difference of the Times. But the same Times are both here and there, and consequently the same Difference of the Times. Therefore the same Cause determining those Reasons may be assigned. So far I understand something; but he subjoins farther. And the Cause which thus determines the Reason of both effects equal Things in equal Times; for the Motion is uniform; here I begin to be blind and to stumble; the former Difference was assigned for determining the Cause of the Times; but now, because it seemed inconsistent for the Difference of the Times to effect equal Things in equal Times, another Cause of the uniform Motion is substituted; tho' here is not one only, but at least two uniform Motions. Do these agree with one another? Do they effect any Thing? or does himself understand his own Definition, or know how to apply it? But however he concludes; therefore by the next preceding Definitions AB. AC :: AE. AF. From this particular Theorem thus demonstrated, he would seem to deduce, as Corollaries, general Theorems concerning *Proportionals*, which comprehend the general Affections of *Proportionals*, and most of them the same contained in the fifth Element. Who can suffer this, that from one Example a general Doctrine should be drawn; or that those Things may be immediately extended to all Subjects, which can be shewn of any two Lines and two Times? As if all *Proportionality* consisted in Times only and Spaces performed with an uniform Motion.

But to pass by all other Faults of this Method, it seems to have happened to this Man, as it usually does to those, who, when they have looked somewhat long intently upon any Thing of a lively Co-

lour, do seem to see all Things tinged with the same Colour: thus this Philosopher seems more intent upon what *Galileus* has writ concerning equable Motion, or is otherwise fixed upon the Contemplation of Physical Motions, when he refers all Things belonging to Magnitude and Quantity to certain preconceived Species concerning Motion. But in every Thing as it is said, *He who has respect to few Things judges ill.* Therefore Things being so, there is no Reason for us to tarry longer upon this new Method. For it is an Affront put upon *Euclid's* Doctrine to compare it with this.

Next we will concisely handle what a most learned Man proposed in his Geometrical Works. Who assumes it for a Definition, *That Reasons are equal, when the Antecedents divided by the Consequents make equal Quotients.* Which Definition differs nothing from that which *Euclid* uses in the seventh Element for the particular Doctrine of Numbers. But these Things seem to hinder it from being a just and accurate Definition of *Proportionality* taken univervally. *First*, because antecedently to the Doctrine of *Proportionality* (*i. e.* that being not yet constituted) it is difficult to conceive what that Division of Quantities is, or how it is performed; *viz.* what it is for a Line to be divided by a Line, a Body by a Body, a Weight by a Weight, or a Time by a Time. There are indeed a certain Division and Multiplication of Lines and other Quantities, which are of Affinity to those Arithmetical Operations from whence they receive their Name, but these are defined and performed from the Invention of *Proportionals*, and consequently suppose *Proportionality* to be foreknown. Moreover Division is commonly by Arithmeticians defined by the Analogy between the Divisor and the Dividend, Unity and the Quotient.

tient. Therefore the Division or Equality of Quotients resulting from it does not seem so fit for a general Explication of *Proportionality*. Perchance you will say, it is easy enough to conceive what it is for a Line to be so often contained in a Line, a Weight in a Weight, or Time in a Time, nor is any Thing else meant here. Very true; but it is here required for the Terms of the Reasons compared to be represented in Numbers; which raises another Argument against this Method, *viz.* *Secondly*, because it seems to confine *Proportionality to Numbers alone*; and intimates as if the Reasons of Quantities are only comparable with one another, as far as the Quantities themselves are denominated by Numbers. For to consider how often one Thing is contained in another, is the same as to exhibit the Proportion of those Things, or denominate them in Numbers. But though Quantities neither be, nor perhaps can be represented or expressed in Numbers, yet their Reasons may be exhibited, and their *Proportionalities* known, by *Euclid's*, or a like, Method. And since it happens immediately to Quantities as such, and not as they may be signified by Numbers, for Reasons to relate to one another, and consequently to be compared together, therefore it seems more agreeable to the Nature of the Thing for them to be determined in one general Manner, rather as Things abstracted from Numbers, than subjected to them. Moreover, *thirdly*, when the Terms of the Reasons compared are incommensurate, neither the Consequents nor any aliquot Parts of them, can be contained a just Number of Times in the Antecedents, and consequently accurate Divisions cannot be performed, nor any Quotients distinctly comprehensible exhibited. For it is not easy to discern, or demonstrate, when or how Quotients confusedly imaginary are equal to one another.

Wherefore this Definition can hardly be accommodated to particular Uses, which is almost the principal Imperfection of a Definition. In short what was said against *Tacquet's* Method, is equally against this, which in Reality is scarce any Thing different from it.

But the same great Man hints at another Definition; Yet if any (says he) would rather call in the Aid of some Affection for the more convenient Procedure of Demonstrations, I know none better than this; *If four Quantities be proportional, the Product made by the Extreams is equal to the Product made by the Means*, and the contrary. Concerning which I will say nothing further, but that that Affection proposed is not general and adequate to *Proportionals*, according to the received Name. For the drawing or Multiplication of Numbers into themselves, or into other Quantities is proper to Numbers alone; the Multiplication of Lines being performed by Similitude, if it be of one into another, or by a Parallel Motion if into Superficies. But who can conceive Lines to be drawn or multiplied into Bodies, or Weights into Times? Let the two Weights A and B be proportional to the two Times Y and Z, tell me what can be produced from the Weight A drawn into the Time Z; why nothing imaginable. Therefore this Affection is not strictly suitable for a general Definition of *Proportionality*; at least it will not any Way serve for determining the *Proportionality* of Numbers and Lines.

But lastly it now remains for us to pass our Opinion concerning *Borellus's* Method; and lest we should seem to detract from the Merits of so great a Man, we readily acknowledge *first*, that his Doctrine, as far as we can see, is very firm, and built upon a good Foundation. We confess that the principal Affections of *Proportionals* are

rightly deduced and demonstrated by him from his own Definitions and Principles. We deny not but his Method is sufficiently neat and elegant in itself, and if there were no other might by candid Judges be accounted as sufficient and absolute enough: But yet in Comparison with *Euclid's* it will be found faulty, and though it contains in it most Things well, yet these are not so excusable.

First, that since Equality is equally agreeable with all Reasons of Quantities both Effable and Ineffable, and certain universal Properties are congruous with that, yet here every Equality is not defined universally and together, but particularly and successively. For the Equality of Effable Reasons is first defined from some of its own particular Attributes, their Greater and Lesser Effable Reasons from that, and lastly the Equality of Incommensurable Reasons from these. But to what End are all these Distractions of a general Subject, and Goings about by Inferiors, if here can be a general Property (as is exhibited by *Euclid*) of all Kinds of equal (as also unequal Reasons from whence they may be universally dened? If any essential Property can be found in the Genus of Animality, is it not more agreeable to the Nature of the Thing, the Genius of Science and the Rules of good Logic, to define Animality entire and at once, than the Animality of a Man, and the Animality of a Brute separately? It seems so to me.

Secondly, it is not so well to define the Equality of Ineffable Reasons negatively, and so as to suppose the Definitions of Unequal Reasons foreknown. For positive Definitions are universally reckoned preferable to negative ones, as begetting a more noble and clear Knowledge of Things. Then it seems preposterous to determine any Thing concerning Equality from Inequality, that seeming prior, more simple and more stable than this, and entirely indivisible

indivisible in itself. Thus the Ancients; *Equality* (says (a) *Nicomachus*, of itself is inseparable and indivisible. *Damusciu*, *Equality* is analogous to any Station. (b) *Theon Snyr*. *The Reason of Equality* is the chief, the first and the principal of all the said Reasons, and of the Analogies according to the same. Therefore the *Equality of Reasons* seems wrongly to be put after their *inequality*. Has not *Euclid* then done better in defining *Equality* first by a positive Affection, and *Inequality* correspondently from another contrary Affection?

Thirdly, I observe the Prolivity of this Doctrine, which scarce performs that by an Ambages of long Definitions (*viz.* to distinguish the *Equality of Reasons* from their *Inequality*) which *Euclid* effects in only two, and these, if we weigh the Matter well, much shorter and more imple. The same might be observed in the whole Process of their Doctrines, that *Euclid* every where does the Thing with much fewer Syllogisms.

Moreover *fourthly*, I note that whosoever inspects *Borellus's* Propositions and Demonstrations, he will find that the principal Properties of *Proportionalities* in that Method of his are not drawn but by indirect and oblique Argumentations; which too much argues them to be none of the best Principles. *Aristotle* teaches, and all Men allow, that not so clear and convincing a Science is produced by such Reasonings. Nor is it strange that winding and crooked Demonstrations should flow from the Fountains of negative Definitions. Is not *Euclid* then to be preferred, who gathers the same Things from positive Definitions by an immediate and direct Discursus?

Fifthly, what displeases me most, and is in my Opinion most faulty, is the Accommodation of these

(a) *Nicom.* l. 2. Vide *Bull. Nis* in *Theon.* p. 273.

(b) *Theon.* c. 51.

Definitions to particular Subjects, or rather they cannot be fitly so applied. For the *Proportionality* of Things is neither quickly known by the Help of Definitions, nor readily deduced from thence, but is demonstrated from such intermediate Propositions, as are not so easy to be comprehended, being proved by an indirect Argumentation. Look, if you please, into the Demonstrations of the first and last Theorems of the sixth Element (which with *Borellus* are the first of the fourth, and second of the fifth) and you will find it as I say; and perhaps will subscribe to my Opinion, that *Borellus* has no Cause to boast of the Evidence of his Doctrine above that of *Euclid*. For the Evidence of a Doctrine appears chiefly in Use, and an easy Aptness to the particular or special Subjects of the first Definitions; nor is there any greater Virtue in these, than as it immediately appears they agree with the Things subjected. This *Euclid* has most clearly shewn of his, but not *Borellus* of his. Why may we not then pronounce that the Performances of the former are preferable to the Endeavours of the latter however excellent in themselves?

I have briefly taken Notice of these Things, not to derogate any Thing from the Praise of this great Man, but to shew the Excellency of *Euclid's* Doctrine, and at the same Time defend the ancient Geometricians following and submitting to him, especially *Archimedes*, the most august Prince of Mathematicians, who subscribes to him, as often as Occasion requires.

I add, and close up this designedly limited Disputation, with this Attestation, that, in my Judgment, there is nothing extant in the whole Work of the Elements more subtilly invented, more solidly established, or more accurately handled than the *Doctrine of Proportionalities*. Which was chiefly
in

in my Mind to declare, when I entered upon this
Contemplation and Theory concerning *Reasons* and
Analogies. Of which Work I must now take my
Leave, but am sorry it has fallen out contrary to
my Hopes and Intentions, that I can neither com-
pleat this whole Subject of *Proportionality*, nor pro-
pose what follows concerning the Determination,
Similitude, and Generation of Magnitudes : Things
perhaps neither unprofitable nor unpleasant. There-
fore these are to be reserved or suppressed, as we shall
see Cause hereafter. In the mean Time, most candid
Auditors, I leave you to the Protection of the good
God.

Their Necessity in laying the first Foundation of any Science, 199. Equivocal and synonymous, 218, 219. From the Generations of Magnitudes, 223. Their Laws, 400, 411, 417. Positive preferable to Negative, 87, 437.
- Demonstration* mathematical, its Excellency, 52, &c. 80, 81. Scientific and Causal, 80, 83, &c. None from external Causes to their Effects, and *è contra*, 88, 89. Simple and

The I N D E X.

- compound, 94. Its Premises, 102. How made perfect, 104. Supposes the Existence of God, 109, 110. May be of Things having no Existence, 110. Direct preferable to oblique, 438.
- Dialing*. See *Gnomics*.
- Difference*, its Signification in arithmetical Proportions, 321.
- Diopters*, what, 18.
- Dioptrics*, what, 17, 18, 24.
- Divisibility* infinite of Magnitude, 151, &c. Received by *Plato*, *Aristotle*, *Chrysippus*, and all the Stoics, and by *Cartesius*, 152. Objected against by *Epicurus* and his Followers, 156, &c. By *Zeno*, 161.
- E.
- Empedometry*. See *Planometry*.
- S. *Empiricus*, his Acceptation of the Word *Mathematics*, 2.
- Equality*, what, 197. Ought to be defined, 200. Of Magnitudes defined alone, 209. Of analogous Quantities separated, 217. An universal Property of Quantity, 437.
- Eratosthenes*, of the Universality of the Doctrine of Proportion, 313.
- Euclid*, promiscuously names all Principles Hypotheses, 125. His Definition of *equal Magnitudes*, 206. Of *Homogeneals*, 298. Of Reason, *ibid.* Most undecently treated, 332, &c. His Definitions of a *Tone* and *Mutation*, 349. His Distinction of Magnitudes into Effable and Ineffable, 355. His Definition of Analogy, 388.
- Eudoxus*, the supposed Composer of the fifth Book of the Elements, 331.
- Euthymetry*. See *Altimetry*.
- F.
- Fabius*, his Notion of Analogy, 386.
- Farbius*, his Singularity about *Homogeneity* and *Heterogeneity*, 312.
- Figures mathematical* do not immediately occur to the Sense, 75. Have a real Existence without the Mind, 76, 77
- Finite* and *Infinite* are strictly speaking Heterogenous, 297.
- Foot*, the smallest Measure in Length among ancient Greeks, 263.
- Freedom* of Judgment used by the Author, 297.
- G.
- Galileus*, his supposed new Science of Motion, 110. His Notion of the Composition of Magnitude, 161, *Gemi-*

The I N D E X.

- Geminus*, his Distribution of the *Mathematics*, 16.
General Things not necessary to be treated of, 240, &c.
Geodesy, what, 17.
Geography, what, 23.
Geometry, what, 11, 247.
Geustics, what 24.
Gnomics, what, 18.
Grammar, by whom first invented, 5.
Grammometry, what, 16.
Graphics, what, 24.
Greater, what, 233, 234.
Guldinus, his Distribution of the *Mathematics*, 20.
- H.
- Haptics*, what, 24.
Harmonics, what, 17, 25.
P. Herigon, his Distribution of the *Mathematics*, 20.
Heterogeneity, whence it arises, 295, &c.
Hippocrates, his Advice to his Son to study *Geometry*, 21.
Hobs, his Notion of *Space*, 140, 179. His Mistake about *Measure*, 268, 304. About *Homogeneity*, 303. His absurd Conclusion concerning the *Homogeneity* of a *Line* and *Time*, 305. His Distinction of a *Quantity* from a *Quantum*, 309. His Objections against *Euclid's* Definition of *Proportionality* answer'd, 415. His confused Definition of *Proportionality*, 431.
- Homogeneity* of *Quantities*, what, 294, 300, &c.
Hydraulics, what, 26.
Hyperlogy, what, 386.
Hypology, what, 386.
Hypotheses mathematical, are evidently possible, 57, 128. Their Possibility deducible by *Sense*, 75. Wherein their *Falshood* consists, 109. The same with *Postulates*, 131.
- I.
- Impenetrability*, what, 182.
Incommensurability not known to the *Vulgar*, 282. What is here meant by it, 285. *Infinite Degrees* of it, 286. Its Cause, 287.
Indivisibles, in reality no such Thing in *Magnitude*, 153, &c.
Induction, what, 68, 75.
Inequality of *Reasons*, how estimated, 373.
Infinity inconceivable, 142, 152.
Intellection, what, 72.
Irrationals. See *Surds*.
Isorrhopics, what, 18, 25.
- K.
- Knowledge*, the threefold Method of attaining it, 3.
Knowledge of Quantity, absolute or primary, 272. Comparative or secondary, 275. Particular, 275. General, 277.

The INDEX.

L.

- Lesser*, what 233, 234.
Limma, what, 365.
Logic, by whom first invented, 5.
Logistics, what, 17, 28.
Logos, its different Significations, 315. By Mathematicians only used to signify *Geometrical Proportion*, 322.
Longimetry, what, 265.

M.

Magnitude, the Subject of Geometry, 13. The only real Quantity, 20. Common to all physical Things, 21. Its Proportions depend not upon the Habitudes of Numbers 37. Its Generations easily imaginable, 61. Has all its Properties alike primary or essential, 134, 182. Its Termination, 142. Its Dimensions, 144. Strictly of one only Species, 146. Its Extension, 147. Its Composition, 148. Its Divisibility, 151. Its Occupation of Space, 163, 180. Two or more Magnitudes cannot fill the same Space in the same Time, 182. Its Affections secondarily referred to analogous Quantities, 210, &c. All *Magnitudes* of the same Classis *homogeneous*, 300, &c.

Heterogeneous Magnitudes what way comparable 338.

Majority, what, 353.
Mathematicians heretofore joined with Soothfayers and Conjurers, 8. Banished out of *Italy*, Ibid.
Mathematics, why so called, 2, &c. The first Science taught in a School, 4, 7. They with Philosophy the principal Study of the Ancients, 6. How stiled by the Ancients, 6, 7. Divided into *pure* and *mixed*, 10, 11. Their Progress, 15, &c. Intelligible and sensible, 19. *Mixed Mathematics*, how far co-extended with Physics, 21 — 26. *Mixed Mathematics* only so many Examples of Geometry, 27. How conversant about their Object, 52, &c. Treat of Things most *simple* and *common*, 53. Use Words most plain and *perspicuous*, 54. Admit no Axioms but what are universally true, 56. Suppose no *Hypotheses* but such as are *evidently possible*, 57. Affect a *Paucity* of Principles, 58. The Generations of their Objects *easily imaginable*, 61. Handle things in the most *accurate Order*, 62. Meddle only with such Things as are *certain* 64. A Science properly so called, 66, &c. All Controversies in the *Mathematics* only about Things remote from

The I N D E X.

- from their Foundation, 237, 238.
- Matter* may be augmented or diminished by God, 169. May preserve its present State, 170.
- Maurolecus*, his Mistake concerning the Difference between Arithmetic and Geometry, 33.
- Maximus Tyrius*, his Compellation of *Connate Ideas*, 70.
- Measure*, its various Acceptations, 248, &c. *Mathematical*, its different Kinds, 253, &c. Not defin'd in the Elements, 262. *Geometrical* strictly so called, 264. Primary, 265. Secondary, 266. Its Properties, 267, &c. Heterogeneous, 269. Natural, 271. Arbitrary, 272. The least most convenient, 274.
- Mechanics*, what, 18, 25.
- Mecometry*, what. See *Longimetry*.
- Medicine*, how far a part of the *Mathematics*, 21.
- Meibomius*, his Definition of *Arithmetical Proportion*, 321. His wrong way of explaining Reason, 334. His tedious Study, 367. His erroneous doctrine about Reasons refuted, 380.
- Mensurability*, what, 266.
- Mensuration*, what, 181. Theoretical, 278. Mechanical, *ibid.* Theoretical and mechanical, 279. Sensible, *ibid.* Analytical, 280.
- Mercennus*, his Query answer'd, how *Reasons* are refer'd to Nothing, 379.
- Metaphysics*, the Treasury of the most general and simple Notions, 39, 105.
- Meteoroscopies*, what, 18.
- Metrics*, *Plato's* Name of Geometry, 34, 245.
- Michael Angelo*, his Opinion of the Existence of mathematical Figures without the Mind, 77.
- Minority*, what, 353.
- Motion* must have a Beginning. Its Termination, 143. Extension, 148. Composition, 150. Impossible without Space, 172. Its Definition, 181. The Measure of Time, 184. Its Computation, 210, &c. Congruity, 214. Uniform and circular the best Measure of Time, 215. Its Equality, 217.
- Multitude*, the Subject of Arithmetic, 10, 11, 15.
- Music*, what, 14, 17, 25.

N.

- Navigation*, (or *Nautics*,) what, 23.
- Nicomachus*, why he makes *Arithmetic* prior to *Geometry*, 39. His wrong Notion of *Arithmetical Proportion*, 325. His Definition of a *musical Space*, 348. His double Dichotomy of *Reasons*, 353.
- Notions connate*, what, 69, 70.

The I N D E X.

- No need of such in speculative Sciences, 115.
- Number*, several ways consider'd, 12. How the same with *Magnitude*, 30. Has no determinate Signification of itself, 34, 35, 159. Homogeneous only capable of Addition, Subtraction and Comparison (*i. e.* Proportion) 36, 234, 296, 339. Differently attributed to Things, 38. Mathematical and metaphysical, 39. Has no Existence distinct from what it denominates, 41. *Integral, fracted* and *furd*, 43. Its Termination, 143. Extension, 148. Composition, 150. Congruity, 216. Equality, 218. *Rational*, capable of expressing few Quantities, 288, 342, 374. All *Numbers* homogeneous, 301.
- Numeration*, what, 41, 42.
- O.
- Optics*, its Division, 17, 24.
- Organopoetics*, what, 18.
- Osphrantics*, what, 24.
- P.
- Pantometry*, what, 245.
- Dr. *Pell* refutes the Quadrature of *Longomontanus*, 280.
- Part*, what, 149, 361.
- Pererius* objects against the Dignity of *Mathematics*, 80. Against the *thirty second* of the *first Element* 97.
- Perspective*, what, 17, 24, 27.
- Philosopher*, a Name not assumed by the Ancients, 5.
- Physics*, their subject, 13. *Effective Physics*, 20.
- Planometry*, what 15, 40, 51, 265.
- Plato*, his Division of the *Mathematics*, 10, 15. Usefulness of the *Mathematics* in *Military affairs*, 22. His Name of *Geometry*, 34, 245. Reprehended by *Aristotle*, 302. His Encomium upon the Doctrine of *Proportion*, 313. Of *Proportionality*, 385.
- Platonic Remembrances*, what, 116.
- Pneumatics*, what, 18, 26.
- Point* opposed to a *Cypher*, 48. Its *Reality*, 145.
- Polioretics*, what, 22.
- Politics*, how far ascribed to the *Mathematics*, 22.
- Posidonius* writes against *Zeno Sidonius*, 67.
- Possibility* of a Thing not proved from its *Imaginability*, 167.
- Postulates*. See *Hypotheses*.
- Powers mechanical*, their Termination, 143. Extension, 147. Composition, 150. Computation, 210. Congruity, 216. Equality, 218.
- Principles, Mathematical*, their *Paucity*, 58. Depend not only upon *Induction*, 75, 115. Their Truth how resolu-

The I N D E X.

- resoluble, 79. Preparatory to all Reasoning, 103, 107. Their primary Condition, 106. Origin, 115. Number 128, 130.
- Principles, Moral*, flow from Appetite, 116.
- Problem*, every possible one reducible to a *Theorem*, 95. Its Analogy with an *Hypothesis*, 129.
- Proclus*, his Reasons for the Name *Mathematics*, 4. Unjustly blames *Apollonius*, 79, 229. His Mistake in the Number of Principles, 123. His Elogium on a *Point*, 146. Received not *Congruity*, 206. His Error upon the eighth Axiom of the *first Element*, 224. His Definition of *Geometry*, 247. His Demonstration of the Homogeneity between rectilinear Angles and some curvilinear ones, 300.
- Projecture*, what, 17.
- Properties of Magnitude*. See *Affections*.
- Proportion*, Universality of its Doctrine, 314. Occasion of the Word, 318.
- Proportion of a Circle to its Diameter* inexplicable in *Numbers*, 287.
- Proportion arithmetical*, what 321. Explained by Subduction, 323, &c. Seems not to have been known to the Ancients, 343. Not known to the Vulgar, 344. In some Cases scarce differs from *geometrical Proportion*, *ibid*.
- Proportion Geometrical* (or *Reason*) between two *negative Terms* is *positive*, 329. None between a *negative* and *positive Term*, *ibid*. Its Definition, 331, 351. Divided into Reasons of *Equality*, and Reasons of *Inequality greater and lesser*, 353. Reasons *effable* or *explicable*, 356. *Ineffable* or *Inexplicable*, *ibid*. Of *Equality*, 358. Of *Inequality* subdivided into five Species, 359. Their Composition, 379. *Multiply Reason*, 381, 382.
- Proportionality*, what, 388, 389. A new Definition of it, 430.
- Propositions immediate*. See *Principles*.
- Propositions universal*, naturally discerned, 72. All such named *Axioms* by the *Stoics*, 125.
- Pythagoras*, his *triple Commentary*, 6. His threefold *Gradation*, *ibid*.
- Pythagoreans*, first Cultivators of the *Mathematics*, 4, 14. Their Division of the *Mathematics*, 14.

Q.

- Quadrature of the Circle*, not impossible in its Nature, 194. What it means, 201.
- Quantity*, the Object of *Mathe-*

The I N D E X.

- Mathematics*, 20. *Continued and discontinued*, *ib.* Its Definition, 151. One less than any Thing assignable, 285. How one differs from another, 296. *Effable and Ineffable*, 355.
- Quantity analogical*. See *Motion, Powers, Numbers, Times, Velocities*.
- Quantity real*. See *Magnitude*.
- Quotity*, (or *Multitude*,) the true Signification of the τὸ ποσόν of *Aristotle*.
- R.
- Ramus*, impertinently carps against *Euclid*, 49, 59, 336, 339, 401.
- Reason*. See *Proportion geometrical*.
- Regiomontanus*, his Deduction of the first Rules of *Arithmetic* from the *Elements* of *Euclid*, 60.
- Rhetoric*, by whom first invented, 5.
- Right Line*, several ways consider'd, 11.
- Rivaltus*, his Argument upon *Archimedes's Postulates*, 126.
- S.
- Scenography*, what, 17.
- Science*, what, 90. *Speculative and practical*, 50. Its Origin, 115.
- Sciography*, what, 17.
- Seneca*, his Account of Mathematicians, 8.
- Sense*, Its certainty, 70. Sometimes deceitful, 71. When rightly disposed, *ibid.* *Mathematical Subjects* do not directly occur to it, 75.
- Similitude* (or *Identity*) of Respect not fit to enter the Definition of *Proportionality*, 428.
- Situation* determinate, what, 181.
- W. Snellius*, his Description of *Congruity*, 187.
- Socrates*, his Severity against such as arrogated the Name of Philosophers, 5.
- Space*, its real Existence denied by *Aristotle, Cartesius*, and others, 163. *Vulgar Notion* of it, 165. Arguments for its real Existence, 166, &c. The Author's Notion of it, 175. The Reasonableness of this Notion, 178. One Way determinate and another indeterminate, 176. Directly opposed to *Contiguity*, 178. Its Analogy with *Time*, 184. Its Notion not more obscure than the Notion of *Equality*, 229.
- Sphere*, several ways consider'd, 23.
- Spherics*, what, 23.
- Spheropoetics*, what, 18.
- Statics*, what, 25.
- Stereometry*, what, 15, 52, 265.

Stevi-

The I N D E X.

- Stevinus*, his geometrical Numbers, 45.
Suidas, his Explication of the Word $\sigma\chi\iota\sigma\iota\varsigma$, 334.
Superficies, their Reality, 145.
Surds, what, 43, 44. Why devised, 357.
Symmetry. See *Commensurability*.
Synthesis, what, 28.
Systematics, what 23.
Thrasylhis, his Definition of a musical Space, 348.
Time, Its Extension, 148. Composition, 150. The Measure of Motion, 184. Computation, 211. Congruity, 215. Equality, 218.
Toricellius, first Inventor of the *Arithmetic of Infinites*, 297.
Trigonometry, what, 51, 265.

T.

- Tacitus*, his Account of Mathematicians, 8.
A. Tacquet, his Definition of *Analogy*, 405.
Tactics, what, 18.
Teachers, ought to define their Words, 204. Have a Right to impose Names, 407.
Term, what, 321.
Thaumastopoeics, what, 18.
Theodosius, his Lemma concerning *Incommensurability*, 285.
Theon, his Definition of a Term, 320. His wrong Notion of *arithmetical Proportion*, 325. His Definition of Reason, 336. Of *Analogy*, 348, 386. Of *Reasons* simply effable, 365.
Theorem, its Analogy with an *Axiom*, 129. every one capable of being formed into a *Definition*, 408.
Theorics, what, 23.

V.

- Velocity*, Its Composition, 150. Computation, 211, &c. Congruity, 214. Equality, 217. Infinite, inconsistent, 301.
Vieta, his Analytical Law, 302.
Vincentius, his Definition of *Reason*, 376.
Vitellius, his Postulate of plane Superficies, 190.
Vitruvius, his Definition of *Symmetry*, 283.
Unequal, what, 233.
Unity, the Origin of *Number*, 43. Not opposed to a point, 48.
Vossius thought *mathematical Figures* to exist only in the Mind, 76.

W.

- Dr. *Wallis*, his Reasons why he makes *Geometry* subordinate

The INDEX.

- dinate to *Arithmetic*, 37,
40. His Mistake about
Geometrical Reasons chang-
ing their *Genus*, 328. Sup-
poses all *Reasons* to exist
in the *Genus* of *Number*,
374.
Weight. See *Powers mecha-*
nical.
Whole, what, 149.
Wisdom, the fivefold Me-
thod of attaining it, 7.
Writing, by whom invented,
5.
- X.
- Xenocrates*, his Description
of the *Mathematics*, 7.
- Z.
- J. *Zabarella*, his Commem-
dation of *Euclid's Ele-*
ments, 53.
Zeno, his Device against the
Reality of Space, 165.
Zoology, what, 22.
